EXECUTIVE SUMMARY

This report describes Site Inspection (SI) activities performed to assess Munitions Constituents (MC) at three Munitions Response Sites (MRSs) under the Munitions Response Program (MRP) at Former Naval Air Station Brunswick (NASB) Cumberland County, Maine, including the following:

- Machine Gun Boresight Range (MGBR)
- Skeet Range (SKT)

Field activities included MC sampling and analysis of shallow and deep surface soil, subsurface soil, sediment, and surface water samples, and well installation and groundwater samples at MGBR. Tetra Tech NUS, Inc. (Tetra Tech) personnel mobilized to NASB in summer 2009 to initiate the MC investigation. Several field events were required due to various delays (e.g., consensus on fixed-base sampling locations and winter weather). Personnel demobilized in spring 2010 after completion of SI activities. This work was performed by Tetra Tech under Comprehensive Long-Term Environmental Action Navy (CLEAN) Contract Number N62472-03-D-0057, Contract Task Order (CTO) 69.

This document addresses the MC activities associated with the SI. Following MC sample collection and analysis, data management, including data validation and database management, was conducted.

The MC SI work is based on Department of Defense (DoD) and United States Environmental Protection Agency (USEPA) guidance for performing response actions at military ranges (2000), Navy Munitions Response Program Guidance (2005), Defense Environmental Restoration Program (DERP) Management Guidance (2001), USEPA Guidance for Performing Site Inspections (1992), and applicable United States Army Corps of Engineers (USACE) guidance on ordnance and explosive response actions (USACE, 2002, 2003a through f, and 2004).

The following recommendations were made for the MGBR and SKT at NASB:

TABLE ES-1

**SUMMARY RECOMMENDATIONS
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK, MAINE**

Machine Gun Boresight Range

Soil: There are two “hot spots” of lead and other metals contamination in surface soil (SB22 and SB01), although the locations are infrequent and sporadic (not adjacent to each other). While it appears that metals contamination is present in soil at and near the former source berm location, the berm material has been removed and the remaining contamination is residual and limited to these two small areas. The two hot spots warrant remediation via excavation and proper disposal.

Groundwater: For groundwater, lead concentrations were not of concern, and only chromium and manganese were detected at concentrations greater than both Maine MEGs and USEPA tapwater RSLs. However, chromium was only a potential concern at one location (MW03); moreover, the concentration of chromium at this location was 35.1 micrograms per liter ($\mu\text{g}/\text{L}$), only slightly exceeding the Maine MEG value of 20 $\mu\text{g}/\text{L}$. While the maximum concentration of manganese, 551 $\mu\text{g}/\text{L}$, was only slightly greater than the Maine MEG of 500 $\mu\text{g}/\text{L}$. There were no analytes detected at concentrations greater than MCLs. The low levels of inorganics found in groundwater do warrant groundwater use restrictions.

Skeet Range

Further characterization of shallow surface soil is recommended for the SKT.

Soil: Shallow surface soil (0 to 3 inches bgs) is contaminated with metals and PAHs (primarily antimony, arsenic, lead, and benzo(a)pyrene) at unacceptable concentrations. The contamination appears to be located within the combined middle area of the pre-1950 and post-1950 range fans overlap. Contamination is present from the firing points extending outward to encompass the shotfall zones in this central area. Additional shallow surface soil sampling to refine the area is recommended.

Analytes for further sampling should include antimony, arsenic, lead, and select PAHs.

Groundwater: Groundwater was not investigated, pending evaluation of soil results. Because only shallow surface soils (0 to 3 inches bgs) are of primary concern, it does not appear that contamination has migrated to deeper soils at concentrations of concern and, therefore, the migration pathway from soil to groundwater is not complete. Therefore, for groundwater no investigation is warranted.

Surface Water: Metals were detected at elevated concentrations in surface water. Further assessment is recommended for the site pond.

Sediment: Metals were detected at elevated concentrations in sediment. Further assessment is recommended for the site pond.

1.0 INTRODUCTION

1.1 PURPOSE OF REPORT

This report describes Site Inspection (SI) activities performed to assess Munitions Constituents (MC) at two Munitions Response Sites (MRSs) under the Munitions Response Program (MRP) associated with the Former Naval Air Station Brunswick (NASB) Cumberland County, Maine (Figure 1-1), including the following:

- Machine Gun Boresight Range (MGBR) (Figure 1-2)
- Skeet Range (SKT) (Figure 1-3)

Field activities included MC sampling and analysis of surface soil, subsurface soil, sediment, and surface water samples, and well installation and groundwater samples at MGBR which were conducted in accordance with the Site Inspection (SI) Work Plan, Munitions Constituents at Three Munitions Response Sites (Tetra Tech, 2009). This work was performed by Tetra Tech NUS, Inc. (Tetra Tech) under Comprehensive Long-Term Environmental Action Navy (CLEAN) Contract Number N62472-03-D-0057, Contract Task Order (CTO) 69.

1.2 SCOPE OF WORK

This document addresses the MC activities associated with the SI. Following MC sample collection and analysis, data management, including data validation and database management, was conducted.

The MC SI work is based on Department of Defense (DoD) and United States Environmental Protection Agency (USEPA) guidance for performing response actions at military ranges (2000), Navy Munitions Response Program Guidance (2005), Defense Environmental Restoration Program (DERP) Management Guidance (2001), USEPA Guidance for Performing Site Inspections (1992), and applicable United States Army Corps of Engineers (USACE) guidance on ordnance and explosive response actions (USACE, 2003a through f, and 2004).

The media sampled at each MRS during the SI are summarized in Table 1-1.

Machine Gun Boresight Range

The MGBR is located on the eastern portion of former NASB and encompasses approximately 0.3 acre from the firing line to the berm, with an approximately 1,029.4-acre surface danger zone (SDZ) during historical operations. The former range was used during the 1950s to align and test fire aircraft-mounted guns. Naval aircraft of the 1950s would have fired .30-caliber and .50-caliber machine gun ammunition. At the time the range was active, the area east of the range was undeveloped and wooded. The range is visible on a 1957 aerial photograph of the installation; however, there are currently no visible remnants of the MGBR or range berm. A map believed to be from the late 1950s to early 1960s found at the National Archives had the range labeled as a pistol range; however, the exact history or use of the range as a pistol range is unknown. In the early 1960s, the layout of the installation was changed, and eventually taxiways connecting the runways to the range area were removed and the range was abandoned. Building 55 and the associated parking lot appear to be located on the approximate area of the compass rose and part of the former range floor; however, the former location of the backstop for the range is not currently covered. The primary MC of concern associated with machine gun and small arms ranges is lead. Other metals of concern included antimony, arsenic, and copper. Perchlorate is also a potential contaminant of concern because every fifth round fired from a machine gun was a tracer round that would have contained pyrotechnics. The MC investigation at MGBR included surface and subsurface soil, and groundwater sampling.

Skeet Range

SKT is located on 78 acres in the southeastern portion of former NASB in an open field approximately 75 meters north and 100 meters east of Building 55. The former range was located adjacent to Range Road just northeast of the taxiway intersection. The former SKT was used for the training of military personnel during the 1950s. Navy Programming Guidance from the 1950s defined the SDZ of a skeet range as a 900-foot radius from the shooting filed. On range maps from 1952, the range is shown with the direction of fire to the north; however, in a 1957 aerial photograph, the range is shown with the direction of fire to the east. It appears that the layout of the range and direction of fire were changed to maintain a safe distance from the shooting field outlined in the Programming Guide because the area east of the range was undeveloped. The primary potential constituent of concern was lead from shotgun ammunition and polynuclear aromatic hydrocarbons (PAHs) from the clay targets. Other potential MC that were less of a concern included antimony, arsenic, nickel, lead azide, propellants, and plasticizers. The MC investigation at SKT included shallow and deep surface soil, sediment, and surface water sampling.

1.3 OBJECTIVES

The objective of the SI described was to conduct an on-site investigation and gather sufficient data to determine the presence or absence of MC that may remain from activities conducted by the DoD during site operation and that may subsequently pose a threat to human health and/or the environment (Tetra Tech, 2009). Under the MRP, the primary goal of the SI is to collect the appropriate amount of information necessary to make one of the following decisions: 1) whether a Remedial Investigation (RI) is required at a site; 2) whether an immediate response is needed; or 3) whether the site qualifies for no further action (NFA).

1.4 REPORT ORGANIZATION

The following information is contained in this document:

- Section 1.0 discusses the purpose of the report, presents brief MRS descriptions and SI scope information, and summarizes the objectives of the SI.
- Section 2.0 discusses the facility background and physical setting.
- Section 3.0 discusses the general MC SI methodology.
- Section 4.0 discusses the MGBR.
- Section 5.0 discusses the SKT.
- Section 6.0 presents the references used in preparation of this document.

The following appendices are included in this report and provide technical information compiled during the SI:

- Appendix A: Project Personnel Sign-Off Sheet
- Appendix B: Photographic Log
- Appendix C: MC Field Documentation
- Appendix D: Validated Analytical Results
- Appendix E: MC Data Usability Assessment
- Appendix F: X-Ray Fluorescence/Fixed-Base Laboratory Correlation Statistical Evaluation
- Appendix G: Project Action Limits and Screening Levels Supporting Documentation
- Appendix H: Responses to Stakeholder Comments on Draft Version of SI Report

2.0 FACILITY BACKGROUND AND PHYSICAL SETTING

2.1 GENERAL FACILITY BACKGROUND AND PHYSICAL SETTING

2.1.1 Regulatory Framework

The regulatory process for managing Navy MRP sites is guided by a complex mixture of federal, state, and local laws, as well as DoD and Navy regulations and guidance. The key legislation, policy, and guidance directing the program includes, but is not limited to, the following:

- Navy Munitions Response Program Guidance (Navy, 2005), which states that munitions response will be conducted “in accordance with Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).”
- Management Guidance for the DERP (DERP, 2001). The history of the DERP dates back to the Superfund Amendments and Reauthorization Act (SARA) of 1986. The scope of the DERP is defined in 10 United States Code (U.S.C.) 2701(b), which states the following:

“Goals of the program shall include the following: (1) The identification, investigation, research and development, and cleanup of contamination from hazardous substances, and pollutants and contaminants. (2) Correction of other environmental damage (such as detection and disposal of unexploded ordnance) which creates an imminent and substantial endangerment to the public health or welfare or to the environment...”

- Fiscal year (FY) 2002 National Defense Authorization Act (Sections 311 and 312) reinforced DoD’s 2001 DERP Management Guidance by tasking the DoD to develop and maintain an inventory of defense sites that are known or suspected to contain Munitions and Explosives of Concern (MEC) and MC. Section 311 requires DoD to develop a protocol for prioritizing defense sites for response activities in consultation with states and tribes, and Section 312 requires DoD to create a separate program element to ensure that DoD can identify and track munitions response funding. The 2001 Management Guidance for the DERP and 2002 National Defense Authorization Act, described here, established the MRP. The Navy baseline inventory of sites was completed in FY 2002 and was used to establish the sites or Areas of Concern (AOCs) where PAs were needed to further evaluate the potential for MEC and MC.

2.1.2 History

In 2005, NASB was designated for closure under the authority of the Defense Base Realignment and Closure (BRAC) Act of 1990, Public Law 101-510, as amended. BRAC legislation requires that base closure be in full compliance with CERCLA. The operational closure date for NASB is September 15, 2011, and relocation of mission operations to Naval Air Station (NAS) Jacksonville, Florida, began in 2008.

NASB was first commissioned on April 15, 1943 with a primary mission of training British Naval Command pilots. The station carried out a secondary mission of anti-submarine warfare during World War II. The first U.S. squadron to arrive at NASB was an air scouting squadron. When the squadron began operations, the station consisted of only one-half mile of runway and had no hangers or operations tower. When Royal Canadian Air Force crews arrived, construction was still underway on the runways and various other parts of the station. Over the next few years, the station experienced tremendous growth and expansion of available facilities and infrastructure. At the height of its wartime operations, the station supported three auxiliary landing fields, one at Sanford, one at Lewiston, and one at Rockland, Maine.

The base remained active for 4 years and was subsequently deactivated in 1947. The land and buildings were leased jointly to the University of Maine and Bowdoin College as annexes to ease overcrowding caused by the G.I. Bill student influx. The University of Maine and Bowdoin College terminated their leases in 1949, and the station was taken over by the Brunswick Flying Service. At this time, the buildings that had housed military personnel and equipment were put to other uses. Hangar One was converted to a skating rink, Hangar Two and the operations tower were used for a civilian flying school, Hangar Three housed automobiles, ammunitions magazines became mushroom farms, and shrubbery nurseries were located in the northern portion of the station.

Following this period, the station was selected by the Navy as a prime center for development. During the development period, the United States Air Force reached an agreement with the Navy authorizing the construction of an Air Force Control and Warning Facility at the station as a part of the continental circumferential radar screen.

On March 15, 1951, the dormant air station was recommissioned as a Naval Air Facility with the established mission of supporting three land-plane patrol squadrons, one Fleet Aircraft Service Squadron, and a planned future mission as a master jet air station. The station also retained the mission of anti-submarine warfare. In December 1950, the Navy requested funds from Congress to be used for this master jet project. Such a base required dual 8,000-foot runways and two outlying fields, one for gunnery

and one for carrier practice landings. In addition, the Secretary of Defense submitted a request to Congress for approximately \$20,000,000 in June 1951 to be used for additional barracks, officers' quarters, enlisted men's clubs, a control tower, storage, communication buildings, and new galleys and mess facilities.

Following the reactivation period, several new permanent facilities were erected to replace the World War II "temporary" buildings. New facilities included a modern operations tower, three-deck barracks, and a large mess hall. In addition to these facilities, a new enlisted men's club, Navy Exchange, and Bachelor Officers' Quarters were constructed. In 1951, the designation of the facility was officially changed to Naval Air Station, and the Arctic Survival Training School was established in September 1956 to train personnel deploying to the Arctic in north country survival.

To practice rocket and bombing training, the Navy acquired by condemnation Seal Island, located south of the main facility, in 1958. Bombing and rocket training continued through the early 1960s along with anti-submarine warfare training. Units trained at NASB served in action during the Lebanon crisis in fall 1958, when squadrons of Fleet Air Wing Three provided anti-submarine protection for the Sixth Fleet, then operating in the Mediterranean Sea. Also in 1958, a small detachment of Marines of the 2nd Marine Division from Camp Lejeune, North Carolina, was assigned to NASB. In March 1959, the Marine detachment became the Marine Barracks of NASB. The Marine Barracks eventually assumed full surveillance of the entrances from the civilian security police.

The Navy declared Seal Island excess property in 1965 and began to transfer the island to the National Park Service (Department of Interior) through the General Services Administration. The transfer was completed sometime after 1972. Today, Seal Island is in the Formerly Used Defense Sites (FUDS) program managed by USACE.

On July 1, 1971, Commander Patrol Wings United States Atlantic Fleet/Commander Patrol Wing Five established its headquarters at NASB. In the late 1990s, base consolidation efforts resulted in the demolition of surplus buildings around the installation. For over 40 years, six squadrons (Patrol Squadrons 8, 10, 11, 23, 26, and 44) were based at NASB. The BRAC process resulted in the decommissioning of three squadrons (11, 23, and 44), and reserve squadrons VP-92 and VR-62. Through 2009, three patrol squadrons flying the P3 Orion performed their duties at NASB. In addition, two reserve squadrons were also based at NASB along with VPU-1 mission, the Naval Reserve Center, and the Air Reserve Center. NASB also provided support for ships at Bath, Maine, and various northeastern Naval activities.

2.1.3 Location and Setting

The former NASB Main Base is located in Cumberland County, Maine, and comprises approximately 2,834 acres situated between the Androscoggin River and Casco Bay southeast of the town center of Brunswick, approximately 25 miles northeast of Portland, Maine. It is located approximately 5 miles inland from the Atlantic Ocean, and this proximity to the ocean is a major influence on the climate and ecology at the site. It is bordered by Route 123 and Route 1 on the western and northern sides, respectively, and is adjacent to Route 124 on the eastern side. Former NASB was comprised of the Main Base shown on Figure 1-1 and the following five remote properties:

- McKeen Street Housing Complex, located in Brunswick, approximately 3 miles west of the Main Base, which consists of approximately 70 acres of land and improvements.
- Former East Brunswick Remote Radio Transmitter Site, located in Brunswick, approximately 3.2 miles northeast of the Main Base, which consists of approximately 66 acres of land.
- Topsham Annex, located in the Town of Topsham, approximately 4 miles north of the Main Base, which consists of approximately 74 acres of land and facilities. Originally, Topsham Annex consisted of 125 acres; however, 51 acres were transferred.
- Sabino Hill Rake Station No. 1, approximately 0.23 acre of land located near Phippsburg, approximately 14 miles southeast of the Main Base.
- Small Point Rake Station No. 2, approximately 0.23 acre of land located near Phippsburg, approximately 14 miles southeast of the Main Base.

2.1.4 Current Land Use and Anticipated Future Land Use

The NASB is scheduled for closure in 2011, per the 2005 BRAC committee decision. The last aircraft took off on November 28, 2009, and the runways were permanently closed in January 2010. NASB includes undeveloped property with forest and grass cover (for recreational use), redeveloped buildings (for commercial use), and residential areas. Currently, central, southern, and western portions of the SKT will be used for business and technology industries, and the eastern portion will be used for outdoor recreation. MGBR will be used for business and technology industries.

2.2 GENERAL FACILITY PHYSICAL/ENVIRONMENTAL CHARACTERISTICS

2.2.1 Climate

The State of Maine is divided into three major climatic divisions. Former NASB is located in the Coastal Division, which is strongly influenced by its proximity to the Atlantic Ocean to the east and the White Mountains to the northwest. The Atlantic Ocean moderates extremes in temperature and increases the amount of precipitation received by the area. The White Mountains keep considerable snow from reaching the area from the northwest and also moderate temperatures.

Information obtained from the National Climatic Data Center station in Portland, Maine (approximately 25 miles southwest of Brunswick) provides representative climatic data for the area in which the former installation is located. Average temperatures range from 21.7 degrees Fahrenheit ($^{\circ}$ F) in January to 68.7 $^{\circ}$ F in July, with an annual average of 45.7 $^{\circ}$ F. Mean daily maximum and minimum temperatures of 78.8 $^{\circ}$ F in July and 12.5 $^{\circ}$ F in January have been recorded. During extreme conditions, a daily maximum of 100 $^{\circ}$ F in July and a daily minimum of minus 26 $^{\circ}$ F in January have been recorded. There are, on average, 13 days of zero or subzero temperatures per year.

The annual average precipitation is 45.83 inches, with monthly average peaks as high as 5.17 inches in the fall and as low as 2.87 inches in the summer. The annual average relative humidity ranges from 65 and 77 percent. The mean seasonal snowfall is 67.3 inches. Because of the proximity to the Atlantic Ocean, winter precipitation in southern midcoastal Maine is often in the form of rain or wet snow. Fog occurs frequently along the Maine coast at all times during the year except winter. On average, there are 49 days with heavy fog, defined as visibility less than one-fourth of a mile. Days with the possibility of sunshine range from 48 percent in November to 64 percent in August; the annual percentage of days with sunshine is 57.

Prevailing winds are from the south from April to September, from the north in November and December, and from the west to northwest for the remainder of the year. The annual average wind speed is approximately 9 miles per hour (mph), with monthly average wind speeds not varying considerably (7.7 mph in the summer to 10.1 mph in the spring). Strong winds in the winter, generated by coastal storms, can produce abnormally high wind-driven tides. Regional diurnal and seasonal variations may moderately influence wind directions and wind speeds.

2.2.2 Topography

In the developed portion of the former installation, the topography has been altered so that the area is relatively level. Elevations are in the range from 60 to 75 feet above mean sea level (msl). In undeveloped portions of former NASB, slopes vary between 0 and 15 percent. Slopes between 3 and 8 percent are common in the southern and western margins of the former installation. Steeper slopes occur primarily along stream banks and are isolated occurrences on hills, which generally have more gentle slopes. The highest elevations at former NASB occur in the southeastern and southwestern portions of the former installation. A northeast-trending ridge with an elevation of approximately 120 feet above msl occurs near Dyer Corner. A more extensive ridge, Buttermilk Mountain, occurs northeast of Harpswell Cove. At the southern boundary of the former installation at the Harpswell Cove shoreline, the elevation is at sea level. However, elevations rise rapidly to 60 feet above msl.

2.2.3 Regional Geology

The geology of the area around former NASB is characterized by Pleistocene and Holocene unconsolidated sediments overlying Paleozoic bedrock. Thicknesses of surficial unconsolidated sediments vary from as little as a few feet over much of the southern portion of the former installation and along the eastern and western former installation boundaries up to or exceeding 100 feet in the northern half of the former installation and in a glacially scoured sediment-filled trough trending approximately north-northeast to south-southwest through the center of the southern half of the former installation.

As indicated in Weddle (2001), most of the northern portion of the former installation and those areas within the previously described glacially scoured trough are underlain by Pleistocene-aged regressive marine delta deposits described as interbedded sandy and silty units. Individual beds dip gently to the east. Much of the remainder of the former installation is underlain by either Pleistocene-aged marine near-shore deposits (consisting of gravel, sand, or mud), the Presumpscot formation (consisting of massive to laminated silty clays), or, primarily in elevated areas where bedrock is close to the ground surface, thin drift consisting of glacial till and/or thin layers of near-shore deposits. Sediments deposited in freshwater wetlands and recent alluvial material are present locally.

The predominant bedrock type at former NASB is the Ordovician metamorphic Cape Elizabeth Formation, which is described as a rusty-weathering, thinly bedded, micaceous schist or gneiss with interbeds of mica-quartz schist. The Cape Elizabeth Formation underlies all but the northwestern one-third of the former facility. The northwestern portion of the former installation is underlain by the Ordovician

metamorphic Cushing Formation-Peaks Island Member, which is described as a feldspar-quartz-biotite granofels gneiss.

According to Hussey and Marvinney (2002), most outcrop contacts, faults, compositional layering, and schistosity strike north-northeast to south-southwest, and numerous high-angle and thrust faults cut the area around the former installation. Both bedrock formations at the former installation are characterized by very limited primary porosity, generally in the saprolite or weathered zone. Secondary porosity results from structurally controlled fractures and foliations or planes of schistosity. Such structures at the former installation strike north-northeast to south-southwest and dip to the southeast. Hager GeoScience, Inc. (2004) also identified a secondary set of fracturing that trends east to west.

2.2.4 Soil and Vegetation

The United States Department of Agriculture, Soil Conservation Service (USDA-SCS) Soil Survey for Cumberland County, Maine (1974) shows soils in the vicinity of former NASB as belonging to the Windsor-Hinckley-Deerfield Association. These soils are described as deep, excessively drained to moderately well drained, nearly level to steep, and coarse textured. They occur on bottomlands, glacial terraces, outwash plains, and a few hills and ridges. The major soils in the association are rapidly permeable with a seasonal high water table.

Terrestrial vegetation in the undeveloped sections of former NASB consists predominantly of woodland species. The individual stand compositions are the result of a combination of natural seeding, forest management, and planting. Because former NASB's forest management program established timber stands suited to conditions at the former installation, forested areas of the former facility contain the species typical of the New England coastal area. Differences in species composition generally coincide with differences in soil and physiographic conditions. The majority of former NASB's trees are conifers (white pine, pitch pine, hemlock, spruce, and fir), with lesser numbers of hardwoods (oak, maple, ash, poplar, and birch).

2.2.5 Hydrology

Surface water from former NASB ultimately flows to nearby wetlands or to Mere Brook. In developed areas of the former installation, most natural drainage is directed to the storm water system. Former NASB is included in four major drainage basins: the Androscoggin River, Mere Brook, Middle Bay Cove, and Buttermilk Cove. Approximately 74 percent of former NASB is in the Mere Brook-Harpswell Cove watershed. Mere Brook enters former NASB at the northwestern boundary as a natural stream and is

culverted for approximately 0.5 mile under the runways to an outfall to the southeast and then through the southern end of former NASB. Merriconeag Stream and a number of other very small intermittent streams flow into Mere Brook, which flows into Harpswell Cove at the head of the cove. The southern reach of Mere Brook is tidal, and its channel is wide and bordered by extensive tidal flats.

The Androscoggin River is the major surface water body in the Brunswick area. It is one of the three major rivers that drain into the Atlantic Ocean on the Maine coast; the Kennebec River and Penobscot River are the others. Portions of Brunswick are located in the lower Androscoggin River Basin. The Androscoggin River flows to the east along the northern boundary of former NASB and forms the boundary between Cumberland and Sagadahoc Counties. At the closest point, the Androscoggin River is approximately 3,000 feet from the northern boundary of former NASB. Approximately 13 percent of former installation runoff flows into the Androscoggin River watershed, 4 percent flows into Middle Bay Cove (separated from Harpswell Cove by a northeast-trending ridge), and approximately 9 percent flows into the Buttermilk Cover watershed.

2.2.6 Regional Hydrogeology

Groundwater in the area occurs in both unconsolidated overburden and underlying bedrock. The most productive aquifers in the area are the unconsolidated sand and gravel aquifers. Much of the northern half of the former installation is underlain by a significant sand and gravel aquifer, as indicated in Neil and Locke (1999). On the former installation, the presence of this significant sand and gravel aquifer largely correlates with the presence of regressive marine delta deposits. These units are also present north and west of the former installation. The sand and gravel aquifers are reported to yield in excess of 10 gallons per minute (gpm) and may yield in excess of 50 gpm. The specific units are discontinuous and are obscured by development in some areas. Drillers' logs for test borings and water wells on and near former NASB show that the most common sequence encountered includes glacial outwash of variable thickness (5 to 90 feet) overlying glacco-marine clays (Presumpscot Formation). The remainder of the former installation (southern half and western and eastern boundaries) are outside of the area described as underlain by a significant aquifer. These areas either do not contain water within unconsolidated sediments due to the lack of a significant thickness of unconsolidated material, or the units in these areas are sufficiently fine grained that wells installed in these areas yield less than 10 gpm.

Groundwater well yields from wells screened in bedrock beneath and surrounding former NASB vary greatly, from less than 10 to over 50 gpm, with well depths in the vicinity varying between 100 and 500 feet. However, the majority of bedrock wells immediately adjacent to the former installation produce less than 5 gpm. Even these low well yields may prove suitable as residential supply wells for single

residues. Well yields in the crystalline bedrock underlying the former installation are primarily controlled by the presence and connectedness of fracture and joint systems within the bedrock (Loiselle, 2002).

2.3 REGIONAL ECOLOGICAL SUMMARY

2.3.1 Endangered/Threatened Species

No federal endangered or threatened species are listed as being present at former NASB. One state endangered bird species, the grasshopper sparrow, and one state threatened bird species, the upland sandpiper, may exist in grassland habitat at former NASB. The grasshopper sparrow is a small sparrow that inhabits open grassy and weedy meadows, pastures, and plains. The upland sandpiper is a pigeon-sized bird that inhabits open grassland, prairies, and hayfields in breeding season and open country during migration. The state-listed Blanding's turtle and spotted turtle (threatened) may reside in wetlands, vernal pools, or streams on or near the former installation.

As documented in the Integrated Natural Resources Management Plan (INRMP) Department of the Navy (DON) 2006, one state endangered plant species, the clothed sedge, may occur on the former installation. The clothed sedge inhabits dry, semi-open conditions and may exist in the grassland habitat at the former installation. It is a low-growing, herbaceous, grass-like plant, and artificial areas that are routinely cut, such as under electric power lines, often provide suitable habitat.

2.3.2 Wetlands

According to the United States Fish and Wildlife Service, three primary types of wetlands occur at former NASB. The wetland classifications include PFO4E in the north, PUBHh near the center, and PFO1C toward the southwest. All of the wetlands are classified as Palustrine systems, which include all nontidal wetlands dominated by trees, shrubs, emergents, mosses, or lichens, and all such wetlands that occur in tidal areas where salinity due to ocean-derived salts is less than 0.5 part per thousand (ppt). Wetlands lacking such vegetation are also included if they exhibit all of the following characteristics:

- Are less than 20 acres (8 hectares)
- Do not have an active wave-formed or bedrock shoreline feature
- Have at low water a depth less than 6.6 feet (2 meters) in the deepest part of the basin
- Have a salinity due to ocean-derived salts of less than 0.5 ppt

Wetlands PFO1C and PFO4E are forested and characterized by woody vegetation that is 6 meters or taller. The number one indicates the presence of broad-leaved deciduous trees or shrubs, and the number four indicates that the dominant species are needle-leaved evergreens. These wetland types are seasonally flooded, saturated, and a combination of seasonally flooded and saturated, respectively.

The classification PUBHh includes wetlands with unconsolidated bottoms and a vegetative cover less than 30 percent. The wetland is permanently flooded but has been created or modified by a man-made barrier or dam that obstructs the inflow or outflow of water.

2.3.3 Cultural and Natural Resources

Former NASB is included in the Maine Department of Environmental Protection's (MEDEP) Coastal Zone Management Program, which incorporates regulations regarding development and use of the coastal zone (i.e., point-source discharges, land use, solid waste management, air quality, stream alteration, and spill prevention and control).

A cemetery is located just south of Picnic Pond. An ancient cemetery is located immediately north of the confluence of Merriconeag Stream and Mere Brook.

2.3.4 Water Resources

Former NASB lies within four major drainage basins: the Androscoggin River, Mere Brook, Middle Bay Cove, and Buttermilk Cove. None of the waterways that flow through the former air station are suitable for drinking water supply or recreation (e.g., swimming) [Naval Energy and Environmental Support Activity (NEESA), 1983]. Groundwater serves as the primary source of drinking water for former NASB and the surrounding community, as follows:

- Former NASB drinking water wells: Two water wells which were formerly used by NASB are located at former NASB. One is currently leased to the golf course on the western side of the air station. The other is a bedrock well, which is no longer operating, that supplied drinking water to the guardhouse facilities at Dyer's Gate. Most residents and employees of former NASB obtain their drinking water from an off-base municipal water supply.
- Municipal water supply: Former NASB, residences, and businesses to the north, northeast, and northwest of the former air station obtain drinking water from the Brunswick/Topsham Water District municipal water supply (NEESA, 1983). Groundwater used for the municipal water supply is drawn

from the shallow or overburden aquifer. The closest public well field is the 138 Jordan Avenue well field operated by the Brunswick/Topsham Water District, less than 0.5 mile from the northern boundary of the former air station (USEPA, 1987).

- Private wells: Some people living in the Brunswick community south of the former air station rely on private wells for their drinking water. The most recent complete private well survey, conducted in 1990, identified 23 off-base private wells within a 1-mile radius of the site. Since the survey, a new residence was built on Purington Road, located east of former NASB. This residence has a bedrock private well reportedly used for drinking water. The Maine Geological Survey also maintains drilling information on private wells. Their database identified 12 private bedrock wells located south and east of the former base boundary, including five private wells located on Coombs Road. According to the Maine Geological Survey, the database is not comprehensive and lacks information on other existing wells in the area (Maine Geological Survey, 2005).

3.0 GENERAL METHODOLOGY

3.1 SITE INSPECTION APPROACH

This section describes the sampling design and methods and documentation utilized during the SI field activities performed in December 2009 at the MGBR and SKT located at former NASB. All SI field work was conducted in accordance with the procedures and methodologies described in the Uniform Federal Policy (UFP) site-specific Sampling and Analysis Plan (SAP), which was approved by USEPA and MEDEP (Tetra Tech, 2009). Standard Operating Procedures (SOPs) that governed the field work are included in Appendix A of the approved UFP-SAP.

Project personnel sign-off sheet associated with the SI is provided in Appendix A of this SI report. Sample Log Sheets, field documentation, site photographs, and other supporting information associated with the SI are provided in Appendices B and C of this SI Report.

3.1.1 Site Preparation Activities

Following approval of the UFP-SAP, Tetra Tech personnel began mobilization activities in summer 2009. The field team members reviewed the approved UFP-SAP, associated appendices, supplemental soil sampling work plan, and Health and Safety Plan (HASP) prior to the start of project activities. In addition, the Field Operations Leader (FOL) held a field team orientation meeting to ensure that personnel were familiar with the scope of the field activities.

Prior to collecting any samples at the site, the FOL arrived at the site and began on-site mobilization activities. On-site mobilization activities included the receipt of all field equipment directly from vendors. Upon receipt, each piece of equipment was checked to verify that it was in proper working condition.

3.1.1.1 Permitting/Site Access

All personnel were required to have security clearance for site access. All on-site personnel presented proof of United States Citizenship (i.e., birth certificate or passport), photo identification card, vehicle registration information, and proof of automobile insurance before entry to the facility was allowed.

3.1.1.2 Utility Clearance

Before any intrusive drilling or subsurface sampling activities were performed, utility maps of the facility were obtained from the Navy and thoroughly reviewed. The Navy provided clearance for all site-specific utilities and Tetra Tech pre-marked proposed sampling locations. Predefined coordinates based on the sample location maps were provided to a State of Maine licensed site surveying subcontractor and each location was identified with a pin flag. Locations were moved as necessary to provide proper utility clearance.

3.1.1.3 Mobilization/Demobilization

Tetra Tech personnel mobilized to former NASB in summer 2009 to initiate the MC investigation. The FOL held a field team orientation meeting to ensure that personnel were familiar with the scope of MC field activities. Several field events were required due to various delays (e.g., consensus on fixed-base sampling locations and winter weather). Personnel demobilized in spring 2010 after completion of SI sampling field activities.

3.1.1.4 Vegetation Management

The amount of clearing required at the sites to facilitate sampling activities during SI sampling varied. Hand-held brush cutters/weed eaters (string or blade) were used to clear light vegetation and small grassy areas, and chain saws and a brush hog were used to remove heavier brush and small (less than 2-inch-diameter) trees. Brush/vegetation cuttings were left at each site at the edge of the area cleared.

3.1.2 Field Investigation Methods

3.1.2.1 Hand Auger

The hand auger system consisted of a stainless steel bucket bit (i.e. a cylinder 6.5 inches long and 2.75 inches in diameter), a 3- or 4-foot extension rod, and a cross handle. A properly decontaminated bucket bit was attached to a clean extension rod and then to the cross handle. The area to be sampled was cleared of any surface debris (i.e., leaves, twigs), the hand auger was turned into the ground, and the sample material was removed and placed into a zip-lock bag. This process was repeated until the hand auger reached the final desired depth. Larger debris such as twigs, roots, or stones was removed from the sample. The sample ID, date, time, and depth were marked on the bag with an indelible marker. Excess soil core material was returned to the hole.

3.1.2.2 XRF

Prior to analyzing samples in the field via x-ray fluorescence (XRF) the instrument was standardized in accordance with the manufacturer's instructions, and three known lead concentrations [National Institute of Standards and Technology (NIST) standards] were analyzed to verify the accuracy of the instrument and to assess the stability and consistency of the results.

Sample processing prior to field XRF analysis consisted of homogenizing each soil sample within a large zip-lock bag, removing rocks and other debris and then physically processing the sample material to eliminate clods and produce a fine uniform particle size. Each sample was then transferred to a smaller zip-lock bag from which three separate XRF measurements were made, one from each end and one from the center of the sample zip-lock bag. The average lead concentration of the three readings was used as the final XRF lead concentration for the sample.

During sample collection activities, all soil material was visually inspected in the field for the presence of lead shot or lead shot fragments. The soil material was again visually monitored in the field laboratory during processing for XRF analysis.

3.1.2.3 Direct-Push Technology Drilling

A GeoProbe® rig with a Macro-Core® sampler was the type of direct push technology (DPT) activities during the SI. During DPT drilling, each area to be sampled was cleared of any surface debris, a new clear acetate liner was placed in the detachable Macro-Core® core barrel, and a coring device was attached to the GeoProbe® rig. Macro-Core® samplers (lined with acetate) were driven into the ground to a specified depth using hydraulic pressure. The 0- to 3-inch and 3- to 12-inch soil intervals are considered to be shallow and deep surface soil, respectively; subsurface soil samples were collected at depths greater than 1 foot below ground surface (bgs). The sampler was retracted from the borehole, and the acetate liner and the soil core were removed from the Macro-Core® barrel. The acetate liner containing the soil core was placed in a metal trough, and the acetate liner was cut through its entire length. The soil core was logged on the Soil Boring Log Sheet, and the desired interval of the soil core was placed in a sealable polyethylene bag. The sample material was thoroughly homogenized, and the sample ID, date, and time were written on the bag with an indelible marker. The required information was completed on the Soil Sample Log Sheet, and a chain-of-custody form was updated. The steps were repeated for the next depth intervals, if required. The depth to water table, if encountered, was recorded on the Boring Log, and the estimated moisture content of the soil and the presence or absence of water in the boring were noted. All soil core materials were returned to the hole, and if insufficient soil was

available to fill the hole to the ground surface, bentonite pellets mixed with the soil were used to backfill the hole and hydrated per manufacturer recommendations. All soil sampling equipment was decontaminated prior to collecting the next sample. Appendix C includes completed Soil Boring Log Sheets and Soil Sample Log Sheets, respectively.

3.1.2.4 Soil Boring Advancement

Soil borings at MGBR (NASB-MGBR-MW01 through NASB-MGBR-MW05) were drilled using a DPT rig in preparation for monitoring well installation and to assess lithology. A Tetra Tech geologist observed the soil boring program activities and documented findings.

Soil samples were collected continuously to the maximum depth of each boring with a GeoProbe® Macro-Core® piston rod soil sampling system or dual-tube soil sampling system. The Macro-Core® samplers consisted of a 1.5-inch inside diameter (ID) 5-foot long core barrel with a clear plastic liner, and the dual-tube samplers consisted of a 1-inch ID 5-foot long core barrel with a clear plastic liner. As each sampler was opened, an aliquot was collected for jar headspace screening using a photoionization detector (PID). Headspace screening results are summarized in the boring logs included in Appendix C.

Soil cores were collected at continuous 5-foot intervals from each boring. Soil samples collected from soil borings for head space analysis were collected directly from the acetate liner. Soil cores were characterized according to the Unified Soil Classification System (USCS), and Soil Boring Logs Sheets are presented in Appendix C.

3.1.2.5 Monitoring Well Installation

All new monitoring wells were completed in the overburden, with the well screen intervals selected to intersect the groundwater table. Copies of Well Construction Logs are provided in Appendix C.

Manufactured pre-packed well screens consisting of 2.5-inch outer diameter (OD), 1-inch ID flush-threaded, Schedule 40 polyvinyl chloride (PVC) machine-slotted well screen (0.010-inch slot openings) with silica sand surrounding the well screen were utilized for each new well. Two 5-foot-long pre-packed well screens were threaded together for three of the wells to create 10-foot-long well screen intervals. Each monitoring well was fitted with a bottom plug. Steel outer protective casing (4.5-inch ID by 5-feet long) was installed and grouted in place around NASB-MGBR-MW05. The four remaining monitoring wells were finished with 4.0-inch ID by 8-inch long flush mount road boxes grouted in place. New monitoring wells were locked with keyed-alike locks.

A black mark was drawn onto the top of the PVC well riser, using a permanent marker, to serve as a reference point for the well survey and groundwater depth measurements upon completion of each well. The horizontal and vertical locations of all new wells were surveyed following the completion of well construction (see Section 3.1.7).

3.1.2.6 Well Development

The newly installed wells were developed using a peristaltic pump. Fine-grained material around the pre-packed well screen was drawn into the well using the peristaltic pump and removed by agitating the well water while simultaneously pumping water from the well at a discharge rate of approximately 0.1 gpm.

Groundwater extracted from the new monitoring wells during development was monitored for turbidity at 5- to 10-minute intervals. In accordance with the SAP, well development continued until the turbidity was less than 10 nephelometric turbidity units (NTUs) or well development was performed for 2 hours, whichever occurred first. Turbidities in all wells stabilized at less than 10 NTUs within approximately 1 hour from the start of development. Additional details regarding well development is provided on the log sheets in Appendix C.

3.1.2.7 Water-Level Measurements

Water-level measurements were collected for each site from newly installed wells. Well construction sheets are provided in Appendix C. The synoptic water-level measurements were collected within a short time period (maximum 4 hours) for each of the two events. Measurements were taken with an electronic water-level indicator using the top of the riser as the reference point for determining depths to water in each well. Water-level measurements were recorded to the nearest 0.01 foot on groundwater-level measurement forms provided in Appendix C.

3.1.3 Site Sampling Operations

3.1.3.1 Surface and Subsurface Soil

Shallow surface, deep surface, and/or subsurface soil samples were collected at all three sites for chemical analysis (site-specific) and lithologic analysis. Samples from selected intervals were sent for fixed-base laboratory (FBL) analysis in accordance with the UFP-SAP (Tetra Tech, 2009). Depending on depth of a sample and need to collect lithology information, a variety of sampling methods were used

including DPT, polyethylene scoop, and hand auger. Upon advancement to the planned depth and completion of soil sample collection, borings were backfilled with native soil core material.

Boring logs and Soil Sample Log Sheets are provided in Appendix C.

3.1.3.2 Sediment

During sediment sampling, vegetative matter or debris, if present, was removed from the sample location prior to using a stainless steel hand auger. Sediment samples collected were a composite of two samples to help improve characterization. Three sediment samples (SD02 through SD04) were collected from a retention pond located at the SKT using a 6 by 6 inch Wildco Ponar Sample Dredge. One sediment sample (SD01) at the SKT located in a tributary stream flowing into the retention pond was collected using a stainless steel hand auger. All sediment samples were collected to a depth of 6 inches. Samples were homogenized, decanted if necessary, and transferred into appropriate bottleware. The sample ID, date, time, and sampler initials were written on the bottleware with an indelible marker. Required information was completed on the Sediment Sample Log Sheet and the chain-of-custody form was updated. Appendix C includes Sediment Sample Log Sheets.

3.1.3.3 Surface Water

Surface water samples were obtained using a Kemmler sampler or direct dip and polyethylene gloves. Surface water samples were co-located with sediment samples and collected in accordance with Tetra Tech SOP S12 (SA-1.2). Three of the four surface water samples, from impoundment ponds at SKT, were composite samples. The composite surface water samples were collected in the middle of the water body and from the mid to deep portion of the water column where there is direct interaction with contaminants in the sediment. The fourth sample was a grab sample from the tributary stream. The samples were collected and placed directly in the appropriate sample containers, labeled, and placed in an ice chest chilled to a maximum temperature of 4 degrees Celsius (°C). Water quality parameters such as temperature, pH, specific conductance, dissolved oxygen (DO), and salinity were measured during sample collection using a YSI Model 650 MDS water quality meter and flow-through cell. Turbidity was measured using a Lamotte 2020. Analytical laboratory analysis was site-specific. Copies of Surface Water Sample Log Sheets are included in Appendix C.

3.1.3.4 **Groundwater**

Groundwater samples were collected using USEPA low-flow purging and sampling procedures. Fluid produced during sampling was containerized in 55-gallon drums and stored in the Hazardous Material Building (Building 45) on base until characterized and transferred for off-site disposal.

Peristaltic pumps with dedicated 1/4-inch OD Teflon tubing was used for groundwater sampling. The monitoring wells were purged at flow rates between 200 and 500 milliliters per minute (mL/min), depending on the drawdown observed during purging. Water quality parameters including pH, temperature, oxidation/reduction potential (ORP), specific conductance, turbidity, and DO were monitored at 5- to 10- minute intervals during groundwater sampling. Low-flow sampling continued until pH, temperature, specific conductance, and turbidity had stabilized in each of the wells. Groundwater samples were placed in laboratory supplied containers and shipped to the laboratory for analysis.

Boring logs, temporary well construction forms, and groundwater purge and Sample Log Sheets are provided in Appendix C.

3.1.4 **Quality Assurance/Quality Control Samples**

Quality assurance/quality control (QA/QC) samples were generated during SI sampling activities to monitor both field and laboratory procedures, in accordance with the approved UFP-SAP. QA/QC samples included field duplicates, equipment rinsate blanks, and temperature blanks (Table 3-1). Duplicate sample analysis and the locations where they were collected are summarized in the site-specific sections of this report. The following types of QA/QC samples were collected during the SI:

- Field Duplicates consisted of a single sample split into two portions. Field duplicates were collected at the rate of 1 in 10 during this field investigation to assess the overall precision of the sampling and analysis program.
- Equipment Rinsate Blanks were obtained under representative field conditions by collecting the rinse water generated by running analyte-free water through or over sample collection equipment after decontamination of reusable sample collection equipment and before use. Equipment rinsate blanks were analyzed for the same chemical constituents as the associated environmental samples.

- Temperature Blanks were used to determine if samples were adequately cooled during shipment. One temperature blank was submitted to the laboratory in each cooler, and the temperature was checked upon receipt at the laboratory.
- Field Blanks were collected to assess contamination resulting from field conditions during sampling.

Sample log sheets were generated for each QA/QC sample and are provided in Appendix C.

3.1.5 Field Sample Documentation

The sample numbering scheme and sample labeling was in accordance with the UFP-SAP. Sample documentation consisted of the completion of Sample Log Sheets, chain-of-custody forms, field logbooks, and health and safety documentation. The Sample Log Sheets contain information such as sample location and sample ID number, container requirements and analyses performed, and sample type, time, and date. Any unusually circumstances encountered during sample collection were noted on the form. Chain-of-custody forms (Appendix D) were used to track each sample from collection in the field to receipt and analysis at the laboratory.

3.1.6 Sample Handling, Packaging, and Shipping

Sample containers, preservation, packaging, and shipping were in accordance with the UFP-SAP. All sample containers shipped to the laboratory were sealed in plastic zip-lock bags, placed in a cooler lined with a large plastic garbage bag, and covered with ice. A temperature blank was placed in each cooler prior to shipment. The plastic garbage bag was sealed with tape, and the chain-of-custody form was sealed in a zip-lock bag taped to the inside of the cooler lid. A signed and dated custody seal was applied to each end of the cooler and then covered with strapping tape to provide a tamper-evident seal. A FedEx® air bill was applied to the shipping cooler. Tetra Tech maintained custody of the samples until they were relinquished to FedEx®. All samples were shipped to the laboratory for overnight delivery and were received within sample holding times.

Laboratory sample custody procedures (receipt of samples, archiving, and disposal) were in accordance with Empirical Laboratories, LLC, SOPs.

3.1.7 Surveying

A State of Maine licensed surveyor documented the horizontal locations and elevations of all soil and groundwater sample points. Survey control was maintained by tying into the Maine State Grid coordinate

North American Datum (NAD) 83 West Zone for horizontal datum and the North American Vertical Datum (NAVD) 1988 system for vertical datum. Surveyed features were horizontally located to within +/-0.01 foot and vertical accuracy was +/-0.01 foot. A global positioning system (GPS) unit was used to locate surface water and sediment sampling locations. Appendix C provides SI survey data.

3.1.8 Decontamination Procedures

Small reusable (non-dedicated) sampling equipment (e.g., ponar dredge, kemmler sampler, hand auger) was decontaminated prior to beginning sampling and between sample locations in accordance with the UFP-SAP using potable and deionized (DI) water with Liquinox detergent. Large drilling equipment was steam cleaned.

At the conclusion of SI field activities, the FOL completed a final decontamination of all non-drilling equipment, which was then shipped back to the appropriate vendor(s).

3.1.9 Investigation-Derived Waste Handling

Investigation-derived waste (IDW) materials generated during the field investigation included soil cuttings, excess soil sample material, wash water from steam cleaning, decontamination fluid, spent calibration fluid, and well purge fluid. IDW was containerized into 55-gallon drums and stored at the hazardous material building (Building 45) on base. The three containers (one aqueous and two solid) of IDW were labeled with points of origin and dates collected (note the MGBR and SKT field investigation was completed concurrently with that conducted at Topsham Annex Skeet Range (TASKT); therefore, IDW described herein was combined for these three sites). ENPRO was subcontracted to characterize, transport, and dispose of the IDW generated during the investigation. On March 15, 2010, two drums of aqueous IDW and one drum of solid IDW were removed from the hazardous material building and transported under a bill of lading to the ENPRO Services, Inc., facility in South Portland, Maine, for disposal as non-hazardous waste.

3.1.10 Record Keeping

SI records include field forms, included in Appendix C, chain-of-custody forms, included in Appendix D, and field log books. Information recorded daily in field logbooks included field activities, weather conditions, identity and arrival and departure times of personnel, management issues, etc.

3.2 ANALYTICAL METHODOLOGY

3.2.1 Analytical Methods

Chemical analysis for Target Analyte List (TAL) Metals (SW-846 Method 6010B), propellants [dinitrotoluene (DNT) and nitroglycerin] and explosives analysis by SW-846 Methods 8330A and 8332, total organic carbon (TOC) (Lloyd Kahn Method), pH (SW-846 9046D), cation exchange capacity (CEC) (SW-846 9081), and PAHs (USEPA Method 8270C SIM) were performed by Empirical Laboratories, LLC, of Nashville, Tennessee and perchlorate chemical analysis in groundwater (USEPA Method 6850 with filtration at the laboratory) was performed by Columbia Analytical Services of Rochester, New York under approval by the Naval Facilities Engineering Service Center (NFESC).

3.2.2 Data Usability General Methodology

Data review processes were used to determine whether analytical laboratory data were of acceptable technical quality for use in decision making. The review began with data validation, which is a comparison of data quality indicators (DQIs) to prescribed acceptance criteria. The DQIs used are measures to assess the bias and precision of the analytical calibrations and sample analyses. The output of this review was a set of alphabetic flags such as U, J, R, or combinations thereof that may have been assigned to individual results based on the validation effort. These flags were used to infer the general quality of the data. Also evaluated were the measures of data completeness, sensitivity, comparability, and representativeness. Validated analytical results are provided in Appendix D, and the MC data usability report is provided in Appendix E.

3.2.3 Data Validation Process

Data validation conducted to evaluate false positives included evaluations of data completeness, holding time compliance, calibrations, field QC and laboratory-generated blank results, field duplicate precision, and detection limits for the data collected during the SI. The data packages provided by the analytical laboratory are expansive enough to allow future complete formal data validation, if necessary.

Assignment of data qualification flags conformed to USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review (2008), and USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Validation (2004) guidelines to the greatest extent practicable for non-Contract Laboratory Program data. Data validation specifications require that various data qualifiers be assigned when a deficiency is detected or when a result is less than its detection limit.

If no qualifier is assigned to a result that has been validated, the data user is assured that no technical deficiencies were identified during validation. The qualification flags used are defined as follows:

U – Indicates that the chemical was not detected at the numerical detection limit (sample-specific detection limit) noted. Non-detected results from the laboratory are reported in this manner. This qualifier is also added to a positive result (reported by the laboratory) if the detected concentration is determined to be attributable to contamination introduced during field sampling or laboratory analysis.

UJ – Indicates that the chemical was not detected; however, the detection limit (sample-specific detection limit) is considered to be estimated based on problems encountered during laboratory analysis. The associated numerical detection limit is regarded as inaccurate or imprecise.

J – Indicates that the chemical was detected; however, the associated numerical result is not a precise representation of the concentration that is actually present in the sample. The laboratory reported concentration is considered to be an estimate of the true concentration.

UR – Indicates that the chemical may or may not be present. The non-detected analytical result reported by the laboratory is considered to be unreliable and unusable. This qualifier is applied in cases of gross technical deficiencies (e.g., holding time missed by a factor of two times the specified time limit, severe calibration non-compliance, and extremely low analyte recovery).

R – Indicates that the chemical may or may not be present. The positive analytical result reported by the laboratory is considered to be unreliable and unusable. This qualifier is applied in cases of gross technical deficiencies.

The preceding data qualifiers may be categorized as indicative of major or minor problems. Major problems are defined as issues that result in the rejection of data and qualification with UR or R qualifiers. These data are considered invalid and are not used for decision-making purposes unless they are used in a qualitative way and the use is justified and documented. Minor problems are defined as issues resulting in the estimation of data and qualification with U, J, and UJ qualifiers. Estimated analytical results are considered to be suitable for decision-making purposes unless the data use requirements are very stringent and the qualifier indicates a deficiency that is incompatible with the intended data use. A U qualifier does not necessarily indicate that a data deficiency exists because all non-detect values are flagged with the U qualifier regardless of whether a quality deficiency has been detected.

3.2.4 Data Validation Outputs

After data were validated, a list was developed of non-conformities requiring data qualifier flags used to alert the data user to inaccurate or imprecise data. The reviewer then prepared a technical memorandum presenting qualification of the data, if necessary, and the rationale for making such qualifications (see Appendix E). The net result was a data package that had been carefully reviewed for its adherence to prescribed technical requirements. Pertinent quality estimates are summarized in a more quantitative format in the following section.

3.2.5 Data Quality Review

DQIs are parameters monitored to help establish the quality of data generated during an investigation. Some of the DQIs are generated from analysis of field samples (e.g., field duplicates), and some are generated from the analysis of laboratory samples (e.g., laboratory duplicates). Individually, field and laboratory DQIs provide measures of the performance of the respective investigative operations. During data validation, individual QC results were evaluated. If individual QC results were acceptable, no validation flag was assigned to an analytical result; otherwise, a flag indicating the type of QC deficiency was assigned to the result.

3.2.5.1 Completeness

Completeness is a measure of the number of valid samples or measurements that are available relative to the number of samples or measurements that were intended to be generated. For this project, completeness was measured on two different bases:

Samples collected - measure of the usable samples collected compared to those intended to be collected.

Laboratory measurements - measure of the amount of usable valid laboratory measurements per matrix for each target analyte.

Usable valid samples (or results) were those judged, after data assessment, to represent the sampling populations and to have not been disqualified for use through data validation or additional data review. Completeness was determined using the following equation:

$$\%C = \frac{V}{T} \times 100$$

where %C = percent completeness
V = number of samples (or results) determined to be valid
T = total number of planned samples (or results)

3.2.5.2 Sensitivity and Quantitation Limits

Sensitivity is a comparison of the project quantitation limit goals (PQLGs) to the laboratory's method detection limits (MDLs) listed in Worksheet #15 in the UFP-SAP (Tetra Tech, 2009).

3.2.5.3 Accuracy

Accuracy requirements for field measurements are typically ensured through control over sample collection and handling and through routine instrument calibration. Field accuracies were monitored with blanks to detect cross-contamination and by monitoring adherence to procedures that prevent sample contamination or degradation. Equipment rinsate blanks were collected during the SI to assess cross-contamination via reusable sample collection equipment. The blanks were obtained under representative field conditions by collecting the rinse water generated by running analyte-free water through sample collection equipment after decontamination and before use. The rinsate blanks were analyzed for the same chemical constituents as the associated environmental samples.

Accuracy in the laboratory was measured through the comparison of a spiked sample or laboratory control sample (LCS) result to a known or calculated value and was expressed as a percent recovery (%R). It was also assessed by monitoring the analytical recovery of select surrogate compounds added to samples that are analyzed by organic chromatographic methods. LCSs were used to assess the accuracy of laboratory operations with minimal sample matrix effects. Matrix spike (MS) and surrogate compound analyses measure the combined accuracy effects of the sample matrix, sample preparation, and sample measurement. LCS and MS analyses were performed at a frequency of 1 per 20 associated samples of like matrix. Laboratory accuracy was assessed by comparing calculated %R values to accuracy control limits specified by the laboratory using SW-846 methods.

Percent recovery is calculated using the following equation:

$$\%R = \frac{S_s - S_o}{S} \times 100$$

where %R = percent recovery
S_s = result of spiked sample
S_o = result of non-spiked sample
S = concentration of spiked amount

3.2.5.4 Precision

Precision is a measure of the degree to which two or more measurements are in agreement and describes the reproducibility of measurements of the same parameter for samples analyzed under similar conditions. Precision for chemical parameters is expressed as a Relative Percent Difference (RPD), which is defined as the ratio of the difference to the mean for the two values being evaluated. RPDs are used to evaluate both field and laboratory duplicate precision and are calculated as follows:

$$RPD = \frac{|V_1 - V_2|}{(V_1 + V_2)/2} \times 100$$

where RPD = relative percent difference
V₁, V₂ = two results obtained by analyzing duplicate samples

The precision estimates obtained from duplicate field samples encompass the combined uncertainty associated with sample collection, homogenization, splitting, handling, laboratory and field storage (as applicable), preparation for analysis, and analysis. In contrast, precision estimates obtained from analyzing duplicate laboratory samples incorporate only homogenization, sub-sampling, preparation for analysis, laboratory storage (if applicable), and analysis uncertainties.

3.2.5.5 Comparability

Comparability is defined as the confidence with which one data set can be compared to another (e.g., among sampling points and among sampling events). Comparability was achieved by using standardized sampling and analysis methods and standardized data reporting formats. Comparability of field data was guaranteed by following the UFP-SAP (Tetra Tech, 2009), and comparability of laboratory measurements was achieved primarily through the use and documentation of standard sampling and analytical methods. Results were reported in units that ensured comparability with previous data and with current state and federal standards and guidelines. Comparability of laboratory measurements was assessed primarily with QC samples and through adherence to the laboratory's QA plans.

3.2.5.6 Representativeness

Representativeness is an expression of the degree to which data accurately and precisely depict the actual characteristics of a population or environmental condition existing at the site. The UFP-SAP (Tetra Tech, 2009) and use of standardized sampling, sample handling, sample analysis, and data reporting procedures were designed so that the final data would accurately represent actual site conditions. It is believed that all reported data are adequately representative of site conditions.

3.3 CORRELATION BETWEEN XRF AND FIXED-BASE LABORATORY DATA

Using data from samples analyzed in the field using XRF and also at the FBL, a regression analysis was conducted to evaluate the correlation between the FBL lead results and XRF lead results. To evaluate the regression analysis, the Pearson Correlation and Rsquared value were calculated. The Pearson Correlation is a measure of the strength of the linear relationship between two or more variables with a range of -1 to +1. The value of -1 represents a perfect negative correlation (i.e., as one variable decreases the other increases proportionally); whereas, a value of +1 represents a perfect positive correlation (i.e., as one variable increases the other increases proportionally). A value of 0 represents a lack of correlation.

The correlation analysis results for MGBR and SKT are presented in Sections 4.4.1 and 5.4.1 with supporting documentation included in Appendix F.

3.4 DATA COMPARISON TO SCREENING LEVELS AND PROJECT ACTION LIMITS

The screening levels and project action limits (PALs) used to evaluate the chemical concentrations detected in site media and to decide whether further site investigation is warranted are presented in Appendix G. The screening levels evaluated for soil include Residential Soil Regional Screening Levels (RSLs) (June, 2011) and Maine Remedial Action Guidelines for Soil (RAGS) for Multiple Contaminants, all Scenarios and all Pathways (January, 2010). The screening levels evaluated for groundwater include Tapwater RSLs (June, 2011), Federal Maximum Contaminant Levels (MCLs) (January, 2011), and Maine Center for Disease Control (CDC) Maximum Exposure Guidelines (MEG) for Drinking Water (February, 2011). For surface water and sediment samples, screening levels include values established by EA Engineering (EA) (EA, 2006) and other ecological screening levels. Based on the decision-making process set forth in the UFP-SAP, if an analyte concentration in any sample within the study area boundary exceeded screening levels and PALs, the project team evaluated the data and determined whether further investigation was warranted for a given media. If analyte concentrations were less than screening levels and PALs, the project team recommended no further investigation at a given site.

Detailed discussions regarding site-specific data evaluations are presented in Sections 4.4.2 and 5.4.2 of this report.

TABLE 3-1
SUMMARY OF QA/QC SAMPLES
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK, MAINE

Sample Number	Date Collected	Medium	Type	Analyses
NASB-SKT-SO-RB01-121509	12-15-09	Solid	Rinsate Blank: Aluminum Pan/Plastic Scoop/Stainless Steel Hand Auger	TAL Metals, PAHs, Dinitrotoluene, and Nitroglycerine

Duplicate samples are included in site-specific sample tables.

QA/QC = Quality assurance/quality control.

TAL = Target Analyte List.

PAHs = Polynuclear aromatic hydrocarbons.

4.0 MACHINE GUN BORESIGHT RANGE

4.1 SITE BACKGROUND

4.1.1 Historical Information

The MGBR is located in the eastern portion of former NASB and comprises approximately 0.3 acre from the firing line to the berm, with an approximately 1,029.4 acre SDZ. The SDZ is the area extending from a firing point to a distance downrange based on the projectiles fired, it extends lengthwise to the ultimate ballistic distance of the round fired. The SI area of investigation is located from the firing point to near the berm where the majority of fired bullets would have landed. The former range was used in the 1950s to align and test fire aircraft mounted guns. A map of the area from the late 1950s to early 1960s found at the National Archives labels the range as a pistol range. There is uncertainty about the use of the land as a pistol range during that time, and in the early 1960s the layout of the installation was changed and the range was abandoned. The area has been inactive for more than 50 years, and there are no visible remnants of the range or berm.

4.1.2 Munitions Constituents

The sources of potential MC contamination at the MGBR are the former berm area and the area between the firing line and the berm. As a result, metals, propellants, nitroglycerin, and perchlorate could have impacted surface soil, subsurface soil, and groundwater.

4.1.3 Current Land Use and Anticipated Future Land Use

Currently, the site is not in use, except for Building 55 that is leased, but in the future anticipated land use will include redeveloped buildings for business and technology industry use.

4.2 FIELD WORK

4.2.1 Site Field Activities

Surface (shallow and deep) and subsurface soil and groundwater samples were collected and submitted for FBL analysis to determine whether site activities have resulted in contamination of the site and adjacent areas. Table 4-1 provides a summary of the samples collected, including sampling depths, and the analytical program. Survey and synoptic groundwater level data were collected from the wells to determine the groundwater flow direction at the site. The MC sampling locations are shown on

Figure 4-1 and include those locations where XRF and FBL confirmation samples were collected by the USEPA in support of the SI (see Appendix F).

4.2.2 Work Plan Deviations

All SI activities at the MGBR were performed in accordance with the UFP-SAP (Tetra Tech, 2009). An extra groundwater level data collection event was conducted to verify data initially collected since the gradient was unusually flat, resulting in questionable potentiometric contouring.

4.2.3 Field Data Collection

4.2.3.1 Surface and Subsurface Soil Sampling

A total of 29 soil samples [22 surface (up to one 1 foot bgs) and seven subsurface (greater than 1 foot bgs)] were collected from 15 locations during the SI for analysis of TAL metals and nitroglycerin in accordance with the UFP-SAP and as detailed in Table 4-1. Surface soil sample NASB-MGBR-SS07-0003, a background location for both MGBR and SKT, was analyzed for TAL metals and PAHs (results are presented in Appendix D). Surface soil samples were collected from 0 to 3 and 3 to 12 inches bgs, and subsurface soil samples were collected from 12 to 18 inches bgs. Three surface soil samples (MGBR-SS01-003, MGBR-SB05-0003, and MGBR-SB06-0003) were collected using a DPT drill rig with a Geoprobe® Macrocore acetate sleeve. The remaining surface soil samples were each collected with a disposable sterile polyethylene scoop. One surface and two subsurface soil samples were collected at MGBR-SB01 through MGBR-SB07. Four of the subsurface soil samples (MGBR-SB-05-0312, MGBR-SB-05-1218, MGBR-SB-06-0312, and MGBR-SB-06-0218) were collected using a DPT drill rig with a Geoprobe® Macrocore acetate sleeve. The remaining subsurface soil samples were collected with a stainless steel auger.

Boring Logs and Sample Log Sheets are included as Appendix C.

4.2.3.2 Groundwater Sampling

Five soil borings (NASB-MGBR-MW01 through NASB-MGBR-MW05) were advanced at MGBR to install groundwater monitoring wells. Table 4-2 provides a summary of well construction details for the newly installed monitoring wells, and copies of well construction logs are provided in Appendix C. Sections 3.1.2.5 and 3.1.2.6 provide the general methodology for monitoring well installation and well development, respectively. Monitoring well locations were selected to characterize site groundwater quality, and to provide groundwater elevation control points to evaluate site groundwater flow direction.

Well NASB-MGBR-MW01 is positioned at the former firing point, NASB-MGBR-MW03 is located behind the former berm, NASB-MGBR-MW02 and NASB-MGBR-MW04 are located north and south of the former berm, respectively, and NASB-MGBR-MW05 is located east of the former berm. Following development, groundwater samples were collected from the five monitoring wells on December 29, 2009. Field water-quality parameter measurements are summarized on Table 4-3 and provided in Appendix C. Groundwater samples were analyzed for TAL metals, nitroglycerin, and perchlorate.

4.2.3.3 Surveying

A State of Maine licensed surveyor documented the horizontal and vertical locations and elevations of all sample points at the MGBR. Survey control was maintained by tying into the Maine State Grid coordinate NAD83 West Zone for horizontal datum and the NAVD1988 system for vertical datum. Survey elevations for each of the wells are summarized on Table 4-2. Using a Trimble® handheld GPS, Tetra Tech recorded the position of the dirt pile located at the MGBR. The position of the soil pile is presented on Figure 4-1.

4.2.3.4 Synoptic Water Level Measurements

Synoptic water level measurements events were conducted on December 29, 2009 and July 22, 2010, to provide data for an evaluation of overburden groundwater flow direction and hydraulic gradients. General methodology is provided in Section 3.1.2.7. Water level measurements are summarized in Table 4-2 and Appendix C. Monitoring well locations are shown on Figure 4-1.

4.3 GEOLOGY/HYDROGEOLOGY EVALUATION

The topography of the site is generally level, sloping slightly to the northeast from NASB-MGBR-MW-01(58.2 feet above msl) and NASB-MGBR-MW04 (58.21 feet above msl) to NASB-MGBR-MW-02 (57.5 feet above msl) and NASB-MGBR-MW-05 (57.3 feet above msl).

Geologic cross sections were developed for the MGBR based on the site boring logs. Figure 4-2 depicts an east-west cross section (A-A'), and Figure 4-3 depicts a north-south cross section (B-B'). The site is principally underlain by fine to medium-grained sand with trace silt. Thin discontinuous lenses of silt or silt and sand occur at shallow depths (less than 14 feet bgs) in the southwestern portion of the site and at intermediate depths (approximately 14 to 15 feet bgs) in the central portion of the site. The sandy subsurface is consistent with the interbedded sandy and silty units identified in the area.

Groundwater potentiometric surface contour maps were developed for water level measurements collected at the site on December 29, 2009, and July 22, 2010. The additional round of water levels on July 22, 2010, was collected to confirm conditions at the site, based on the groundwater flow directions observed in December 2009. Given the small size of the area under investigation and low hydraulic gradient, some uncertainty may exist for the groundwater flow, specifically for the December 9, 2009 measurements. Figure 4-4 depicts the groundwater potentiometric surface interpreted for December 9, 2009, and Figure 4-5 depicts the groundwater potentiometric surface interpreted for July 22, 2010. Groundwater at the site generally flows from the north and south into the central portion of the site. A westerly component of flow was measured during the earlier December event, whereas, an easterly component was measured during the later July event.

The difference in the east-west component of flow may be attributable to the low hydraulic gradient due to the small difference in head elevations (maximum head difference of 0.34 foot in December 2009 and 0.55 foot in July 2010). The Upper Impoundment Basin (shown to the far north on Figures 4-4 and 4-5) may also influence groundwater flow at the site. Regardless, of the potential uncertainties of groundwater flow, specifically December 2009, the overall groundwater flow for the area is expected to be to the east-southeast toward the retention ponds and/or Picnic Pond based on topography and previous groundwater investigations in the area of MGBR (Sites 11 and 13, south of the MGBR, and Site 9, north of the MGBR).

4.4 ANALYTICAL RESULTS

4.4.1 Correlation Between Field XRF Analysis and Fixed-Base Laboratory Lead Data

XRF data was previously collected by the USEPA in support of this project (Appendix F), so this data, along with FBL data, was examined as part of the SI to determine its usability. To determine whether XRF concentrations could be used to predict FBL concentrations a statistical correlation analysis was conducted. The correlation analysis for the MGBR is presented in Appendix F. Based on the correlation analysis, it was concluded that correlation between the FBL and field XRF results was acceptable for lead and zinc that predicted FBL concentrations could be meaningfully calculated. XRF results were also collected for copper and nickel. A weak linear relationship between the copper and nickel XRF and laboratory concentrations was calculated; therefore, these XRF results were not used to predict laboratory concentrations.

4.4.2 MC Sampling Results and Comparisons with Screening Levels and PALs

This section presents the analytical results of soil and groundwater sampling conducted at the MGBR and comparisons of analytical results to applicable screening levels. A summary of the analytical program for

the SI samples collected at the MGBR is provided in Table 4-1 excluding USEPA results (see Appendix F) and soil and groundwater sample locations are shown on Figure 4-1 (including USEPA locations).

4.4.2.1 Surface and Subsurface Soil

Excluding the USEPA collected samples, 28 soil samples were collected and analyzed for TAL metals. Also, one background soil sample was analyzed for TAL metals and PAHs. An additional 50 XRF samples were collected by the USEPA and 5 FBL samples for correlation purposes. Summary statistics for these soil samples are provided in Table 4-4, and concentrations of analytes detected in at least one soil sample are summarized in Table 4-5. Metals and nitroglycerin were detected at concentrations greater than screening criteria. Positive detections of metals, with the exception of the essential nutrients calcium, magnesium, potassium, and sodium, are presented on Figures 4-6 and 4-7, respectively. Also presented on these figures are positive detections in the background sample (NASB-MGBR-SS07-0003).

Three metals, (cadmium, chromium, and lead) were detected at concentrations exceeding Maine RAGs while nine metals (aluminum, arsenic, cadmium, chromium, cobalt, iron, lead, manganese, and vanadium) were detected at concentrations greater than USEPA RSLs. All concentrations of cadmium, chromium, and lead which exceeded both Maine RAGs and USEPA RSLs were detected in the first 3 inches of soil with the maximum concentrations in samples NASB-MGBR-XRF-SB01 and NASB-MGBR-XRF-SB22. Exceedances of USEPA RSLs were noted at all sample depths up to 1.5 feet bgs. Nitroglycerin was detected in two samples, the original and duplicate sample at NASB-MGBR-SS01-0003, at concentrations exceeding the USEPA RSL.

4.4.2.2 Groundwater

Five groundwater samples were collected and analyzed for TAL metals, nitroglycerin, and perchlorate. Summary statistics for these groundwater samples are provided in Table 4-6, and concentrations of analytes detected in at least one soil sample are summarized in Table 4-7.

Metals were detected in all five wells. Positive detections for metals are presented on Figure 4-8. Chromium and manganese were detected at concentrations exceeding Maine MEGs. Antimony, arsenic, chromium, cobalt, and manganese were detected at concentrations exceeding USEPA tapwater RSLs. There were no exceedances of MCLs. Exceedances of a Maine MEGs occurred in wells NASB-MGBR-MW03 and NASB-MGBR-MW05 while exceedances of USEPA RSLs occurred in all wells. Perchlorate

and nitroglycerin were either not detected in or were detected at concentrations less than screening levels in groundwater samples collected at the MGBR.

4.4.2.3 Data Usability

Data usability was evaluated based on the results of data validation and the data quality review (DQR), which are discussed in Appendix E. Based on the DQR for the MGBR, SI data are of acceptable quality to make decisions on the path forward for the site. The following summarizes the evaluation for the individual DQIs for the MGBR analytical results:

- Validation process - In accordance with the UFP-SAP, full data validation was conducted. Based on the validation results, no data collected for the MGBR were rejected.
- Completeness - Sample collection completeness for all sample types was 100 percent. The sample analytical completeness for all sample types was also 100 percent.
- Sensitivity - All of the non-detected nitroglycerin and mercury groundwater results were greater than corresponding screening. Sensitivity for all other analytes and matrices was sufficient for the purposes of this investigation.
- Laboratory Accuracy - There were no significant laboratory accuracy concerns for the MGBR samples. See Appendix E for discussions on site data qualified due to laboratory accuracy issues and corresponding result biases if any.
- Precision - No significant QC deficiencies were noted. See Appendix E for discussions on site data qualified due to precision issues.
- Comparability - No comparability issues were noted.
- Representativeness - The reported data are adequately representative of site conditions and intended populations at the MGBR.

4.5 CONCLUSIONS

4.5.1 Surface and Subsurface Soil

For shallow surface soil (0 to 3 inches bgs), the metals cadmium, chromium, and lead were detected at concentrations exceeding both MEDEP criteria and USEPA RSLs. Aluminum, arsenic, chromium, cobalt, iron, lead, and manganese were detected at concentrations greater than USEPA RSLs in few samples at depths up to 1.5 feet bgs and vanadium was detected at concentrations greater than USEPA RSLs at depths up to 3 inches bgs.

4.5.2 Groundwater

For groundwater, chromium and manganese were detected at concentrations exceeding both Maine MEGs and USEPA tapwater RSLs. Antimony, arsenic, and cobalt were detected at concentrations that exceeded USEPA tapwater RSLs only. There were no exceedances of MCLs.

4.6 UPDATED CONCEPTUAL SITE MODEL

Malcolm Pirnie developed a Conceptual Site Model (CSM) describing the MGBR and its environmental setting in the Preliminary Assessment (PA) Report (2006). The CSM has been updated based on the findings of this SI and is summarized in Table 4-8. Exposure pathways by which site receptors could be exposed to or contaminated by MC are shown on Figure 4-9, and Figure 4-10 presents a graphical representation of the CSM.

4.7 RECOMMENDATIONS

Soil: There are two “hot spots” of lead and other metals contamination in surface soil (SB22 and SB01), although the locations are infrequent and sporadic (not adjacent to each other). While it appears that metals contamination is present in soil at and near the former source berm location, the berm material has been removed and the remaining contamination is residual and limited to these two small areas. The two hot spots warrant remediation via excavation and proper disposal.

Groundwater: For groundwater, lead concentrations were not of concern, and only chromium and manganese were detected at concentrations greater than both Maine MEGs and USEPA tapwater RSLs. However, chromium was only a potential concern at one location (MW03); moreover, the concentration of chromium at this location was 35.1 micrograms per liter ($\mu\text{g}/\text{L}$), only slightly exceeding the Maine MEG value of 20 $\mu\text{g}/\text{L}$. While the maximum concentration of manganese, 551 $\mu\text{g}/\text{L}$, was only slightly greater

than the Maine MEG of 500 µg/L. There were no analytes detected at concentrations greater than MCLs. The low levels of inorganics found in groundwater do warrant groundwater use restrictions.

X = Indicates sample was collected and analyzed as proposed in the UFP-SAP (Tetra Tech, 2009).

bgs = Below ground surface.

XRF = X-ray fluorescence.

MGBR = Machine Gun Boresight Range.

SS = Surface Soil.

FBL = Fixed-base laboratory.

SB = Soil Boring.

HA = Hand auger.

DPT = Direct-push technology.

TAL = Target Analyte List.

PS = Polyethylene Scoop.

LF = Low Flow (peristaltic pump).

1. Common background location for MGBR and SKT. Results presented in Appendix D.

2. No XRF samples were collected by Tetra Tech as part of the SI. However, the USEPA collected XRF data and FBL confirmation samples in support of the SI, which are included in the evaluation of data. If good correlation was achieved for a given analyte, calculated values were developed (See Appendix F).

1 Maine RAGS, Appendix 3, (Jan, 2010).

2 USEPA residential Regional Screening Level

(June, 2011). Non-carcinogen values are divided by 10.

3 No XRF samples were collected by Tetra Tech as part of the Site Inspection. However, the

TABLE 4-4

**FREQUENCY OF DETECTION IN SOIL
MACHINE GUN BORESIGHT RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK, MAINE
PAGE 2 OF 2**

Yellow Shading - concentration greater than Maine RAGs criterion.

Italics - concentration greater than RSL criterion.

USEPA collected XRF data and FBL confirmation samples in support of the SI, which are included in the evaluation of data. If good correlation was achieved for a given analyte, calculated values were developed (See Appendix F).

4 Minimum and maximum non-detections are for all samples in the data set.

Note: Chromium screening values are for hexavalent chromium.

Note that a sample and its duplicate sample were considered separately when determining the maximum concentration, and the average concentration of a sample and its duplicate were used in determining frequency of detection.

NC = No criterion.

NA = Not available.

J = Value is estimated.

U = Analyte not detected at the reported detection limit.

UJ = Not detected; the detection limit is considered to be estimated.

Yellow Shading - concentration greater than Maine RAGs RAGs criterion.

Italics - concentration greater than RSL criterion.

Note: Chromium screening values are for hexavalent chromium.

1 Maine RAGS, Appendix 3, (Jan, 2010).

2 USEPA residential Regional Screening Level (June, 2011). Non-carcinogen values are divided by 10.

3. No XRF samples were collected by Tetra Tech as part of the Site Inspection. However, the USEPA collected XRF data and FBL confirmation samples in support of the SI, which are included in the evaluation of data. If good correlation was achieved for a given analyte, calculated values were developed (See Appendix F).

J = Value is estimated.

ug/l = Micrograms per liter.

Note that a sample and its duplicate sample were considered separately when determining the maximum concentration, and the average concentration of a sample and its duplicate were used in determining the frequency of detection.

Yellow Shading - concentration greater than Maine MEG criterion.

Italics - concentration greater than RSL criterion.

Note: There are no concentrations greater than MCL criterion.

1 Maine CDC Maximum Exposure Guidelines (MEG) for Drinking Water (February, 2010).

Note: Chromium value is for total chromium.

2 USEPA residential Regional Screening Level (June, 2011).

Non-carcinogen values are divided by 10.

Note: Chromium tapwater RSL value is for hexavalent chromium.

3 Federal Maximum Contaminant Level (MCL) (January, 2011).

Note: Chromium value is for total chromium.

4 Minimum and maximum non-detections are for all samples in the data set.

NA = Not applicable

ug/l = Micrograms per liter.

J = Value is estimated.

U = Analyte not detected at the reporting limit left of the letter.

Yellow Shading - concentration greater than Maine MEG criterion.

Italics - concentration greater than RSL criterion.

Note: there are no concentrations greater than MCL criterion.

1 Maine CDC Maximum Exposure Guidelines (MEG) for Drinking Water (February, 2011).

Note: Chromium value is for total chromium.

2 USEPA residential Regional Screening Level (June, 2011).

Non-carcinogen values are divided by 10. Chromium value is for hexavalent chromium.

3 Federal Maximum Contaminant Level (MCL) (January, 2011).

Note: Chromium value is for total chromium.

TABLE 4-8
CONCEPTUAL SITE MODEL INFORMATION PROFILE
MACHINE GUN BORESIGHT RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK, MAINE
PAGE 1 OF 3

Profile Type	Information Need	Findings
Range/Site Profile	Installation Name	Former Naval Air Station Brunswick
	Installation Location	Cumberland County, Maine
	Range/Site Name	Machine Gun Boresight Range
	Range/Site Location	The site is located in the eastern portion of the former facility adjacent to Building 55 and extends to an open field behind the building.
	Range/Site History	In the 1950s, pilots used the range to calibrate their aircraft-mounted machine guns.
	Range/Site Area and Layout	Pilots fired toward the east into a berm after taxiing down the runway to the compass rose. The range area encompassed 0.3 acre and had an SDZ of 1,029.4 acres.
	Range/Site Structures	A berm appears on the 1957 aerial photograph of the installation. No other range-related structures are discernable from the 1957 photograph. Based on the site walk, any structures that existed when the range was active are no longer present.
	Range/Site Boundaries	North: Building 55, Building 52, and pond. South: Building 50. East: Open field and forested area. West: Parking lot and Orion Street.
	Range/Site Security	There are no security or access restrictions to the site.
Munitions/Release Profile	Munitions Types	Machine gun (small arms) ammunition including 0.50-caliber and 0.30-caliber and pistol ammunition including 0.20-caliber, 0.22-caliber, and 0.38-caliber.
	Maximum Probability Penetration Depth	Small arms, less than 1 foot. Based on the SI results, the target berm was likely removed and residual contamination is minor.
	MEC Density	Not applicable.
	Munitions Scrap/ Fragments/ MDAS	No MEC scrap/fragments were found during the visual survey.
	Associated MC	Soil: TAL metals and nitroglycerin. Groundwater: TAL metals, nitroglycerin, and perchlorate. Note that chromium present in both soil and groundwater is not perceived to be related to MGBR operations, although MGBR should not be discounted as the source, such as a possible source for elevated pH related to a later use.

TABLE 4-8
CONCEPTUAL SITE MODEL INFORMATION PROFILE
MACHINE GUN BORESIGHT RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK, MAINE
PAGE 2 OF 3

Profile Type	Information Need	Findings
	Migration Routes/Release Mechanisms	Erosion: Potential (in non-paved open area). Surface Water Runoff: Potential (in non-paved open area). Human Intervention: Potential (in non-paved open area).
Physical Profile (see Section 2)	Climate	Continental climate with three well-defined seasons. Highest temperatures occur in July (79°F or higher). Coldest temperatures occur in January (21°F or lower).
	Topography	The former Machine Gun Boresight Range is relatively level.
	Geology	Characterized by two primary components: Unconsolidated sediments and Paleozoic bedrock.
	Soil	Suffield-Buxton-Hollis Association. Deep to shallow moderately well-drained to somewhat poorly drained soils with low permeability.
	Hydrogeology	Groundwater is used as the municipal water supply in the residential area north of the installation. Most of the wells in the vicinity are between 101 and 300 feet deep. There are no wells within the boundary of the range.
	Hydrology	Surface water flows off the paved area away from Building 55. The Upper and Lower Impoundment ponds are located north of the site.
	Vegetation	The undeveloped portion of the range is grassy, with various tree species.
Land Use and Exposure Profile	Current Land Use	The site is not in use, except for Building 55 that is leased.
	Current Human Receptors	Current human receptors include: Civilian, visitors, trespassers, and maintenance workers/contractors.
	Current Activities	In the future, the site will include redeveloped buildings for business and technology industry use.
	Potential Future Land Use	In the future, anticipated land use will include redeveloped buildings for business and technology industry use.
	Potential Future Human Receptors	Same as currently planned.
	Potential Future Land Use-Related Activities	No foreseen change to planned use.
	Zoning/Land Use Restrictions	No site specific restrictions or access controls.
	Demographics/Zoning	Cumberland County population density is approximately 50,000 persons per square mile.
	Beneficial Resources	Groundwater is a source of the municipal water supply.
Ecological Profile	Habitat Type	Open field and forested area behind Building 55.
	Degree of Disturbance	Limited to surface activities near Building 55.
	Ecological Receptors and Species of Special Concern	Potential ecological receptors include indigenous species. No species of special concern are known to be present at the site, which is planned for industrial use.

5.0 SKEET RANGE

5.1 SITE BACKGROUND

5.1.1 Historical Information

The SKT is located in the southeast portion of the installation in an open field approximately 75 meters north and 100 meters east of Building 55, as shown on Figure 1-3. The former range was located adjacent to Range Road just northeast of the taxiway intersection and was used for the training of military personnel during the 1950s. Navy Programming Guidance from the 1950s defined the SDZ of a skeet range as a 900-foot radius from the shooting field. The orientation of the site changed over the years, giving it an area of 78 acres. The site is now covered by vegetation and includes an open field on the east and two impoundment ponds within the site that are used for treatment of runway runoff.

5.1.2 Munitions Constituents

The source areas of potential MC contamination at the SKT are in and around the likely shotfall zone and firing points within which metals, propellants (nitroglycerin and DNT), and PAHs could have impacted soil, sediment, and surface water as per Table 5-1. Of note, assessment of the contributory effects from PAHs from the SKT at the impoundment ponds is difficult due to other significant sources of potential PAH contamination including stormwater runoff and treatment of runway runoff that potentially contains PAHs.

5.1.3 Current Land Use and Anticipated Future Land Use

Prior to 1950, the SKT was in a highly developed part of the base and included several buildings, shown on Figure 1-3. After 1950, the SKT was undeveloped except for the northernmost portion, which contains a baseball field and is intersected by Neptune Drive. Planned future land uses include Community Mixed Use, Recreation, and Business and Technology.

5.2 FIELD WORK

5.2.1 Site Field Activities

Shallow and deep surface soil, surface water, and sediment samples were collected and submitted for FBL analysis to determine whether site activities have resulted in contamination of the site and adjacent areas. Table 5-1 provides a summary of the samples collected during the SI, including sampling depths, duplicate locations, and the analytical program and the MC sampling locations are shown on Figure 5-1.

5.2.2 Work Plan Deviations

All SI activities at the SKT were performed in accordance with the UFP-SAP (Tetra Tech, 2009).

5.2.3 Field Data Collection

5.2.3.1 Shallow and Deep Surface Soil Sampling

At the former SKT, 60 soil samples were collected for XRF field analysis and 32 surface soil samples (varying intervals, all less than 1 foot bgs) were collected for laboratory analysis of TAL metals and PAHs, in accordance with the UFP-SAP and detailed in Table 5-1. Eight soil samples located in and around the firing points were also analyzed for nitroglycerin and DNT. Selected soil samples (SKT-SS06, SKT-SS07, SKT-SS08, and SKT-SS19) were analyzed for TOC, pH, and CEC, in addition to nitroglycerin and DNT. Uppermost surface soil samples (with SS prefix) included intervals from 0 to 3 inches bgs. Deep surface soil samples (with SB suffix) included intervals from 3 to 12 inches bgs. Soil Sample Log Sheets are included in Appendix C.

5.2.3.2 Sediment Sampling

Sediment samples were collected following Tetra Tech SOP SA-1.2 from four SKT locations to characterize the sediment (Figure 5-1). Three of the sediment samples (SKT-SD02 through SKT-SD04) were collected from within the Lower Impoundment Pond located at the SKT on April 9, 2010, using a 6- by 6-inch Wildco Ponar Sample Dredge to collect sediment samples to a depth of 6 inches. SKT-SD01 was collected from in a tributary stream flowing into the Lower Impoundment Pond using a stainless steel hand auger. Samples were homogenized, decanted if necessary, and transferred into appropriate bottleware. One Sample Log Sheet was completed for each sediment sample collected (included in Appendix C). Chain-of-custody forms are included in Appendix D. Sediment samples were analyzed for TAL metals.

5.2.3.3 Surface Water Sampling

Surface water samples were collected following Tetra Tech SOP SA-1.2 at four locations co-located with sediment samples from the SKT on April 9, 2010 (Figure 5-1). Surface water samples SKT-SW02 through SKT-SW04 were collected from the Lower Impoundment Pond with a Kemmerer sampler due to the depth of water in the pond. In accordance with the UFP-SAP, these surface water samples were collected from two discrete intervals of the water column and composited. Surface water sample

SKT-SW01 from the tributary stream was collected at a location where the depth to water was less than 2.5 feet; therefore, the Kemmerer sampler could not be used. This sample was collected by directly dipping a dedicated unpreserved bottle into the surface water and transferring the sample into appropriate sample bottles. After collection of surface water samples, the pH, temperature, specific conductivity, DO, salinity, ORP, and turbidity of surface water was measured in situ and recorded on Sample Log Sheets. Field parameter measurements are summarized on Table 5-2 and provided in Appendix C. Chain-of-custody forms are included in Appendix D. Surface water samples were analyzed for TAL Metals.

5.2.3.4 Surveying

A State of Maine licensed surveyor documented the horizontal locations of all soil sample points at the SKT. Survey control was maintained by tying into the Maine State Grid coordinate NAD83 West Zone for horizontal datum. Surveyed features were horizontally and vertically located to within +/-0.01 foot.

5.2.3.5 Visual Inspection

During the SI Tetra Tech performed a visual inspection of the SKT to identify any former structures or areas of clay pigeons or lead shot. No structures were evident. Two areas of pigeon fragments were identified and are depicted on Figure 5-1.

5.3 GEOLOGY EVALUATION

The site is relatively level in the area of the former skeet range high house and low house. The land surface in the area of the shooting field slopes to the north and east toward Upper and Lower Impoundment Ponds, respectively.

Soil borings were advanced to maximum depths of 1 foot at the SKT. Based on the soil boring log information, the shallow subsurface at the site is fine- to medium-grained sand with trace to some silt.

Note that hydrogeology was not investigated based on previous groundwater investigations north (Site 9) and south (Sites 11 and 13) of the SKT. Groundwater is expected to flow to the east-southeast toward the impoundment ponds and/or Picnic Pond.

5.4 ANALYTICAL RESULTS

5.4.1 Correlation Between Field XRF Analysis and Fixed-Base Laboratory Lead Data

To determine whether XRF concentrations could be used to predict FBL concentrations, a statistical correlation analysis was conducted. The correlation analysis for the SKT are presented in Appendix F. The XRF samples and FBL samples were not collected from the same sample at this site. The primary purpose of the XRF for this site was to confirm the location and boundaries of the skeet range; first XRF samples were collected and, at a later date, FBL samples were collected. Therefore, correlations for lead in XRF and FBL samples was expected to be lower than typical. Upon evaluation of the data, there appeared to be two groups of data concentrations; one with XRF concentrations greater than 100 mg/kg and one with XRF concentrations less than 100 mg/kg. Based on the correlation analysis, it was concluded that correlation between the FBL and field XRF data was acceptable and that predicted FBL concentrations could be calculated for samples where the XRF concentrations are less than 100 mg/kg. For samples with XRF concentrations greater than 100 mg/kg, a very weak correlation was noted and XRF concentrations could not be used to predict laboratory concentrations. XRF results greater than 100 mg/kg were acceptable for their primary purpose, to confirm the location and boundaries of the skeet range. XRF results are presented in Table 5-3, calculated lead values are included in the summary statistics Table 5-4 and both XRF values and calculated values are shown in Table 5-5 for the individual samples. See Appendix F for details on the correlation effort.

5.4.2 MC Sampling Results and Comparisons with Screening Levels and PALs

This section presents the analytical results from soil, sediment, and surface water samples collected at the SKT and presents comparisons of analytical results to applicable screening levels. A summary of the analytical program for the SI samples collected at the SKT is provided in Table 5-1, and SKT sampling locations are shown on Figure 5-1.

5.4.2.1 **Shallow and Deep Surface Soil**

Thirty-two soil samples were collected and analyzed for TAL metals and PAHs, and eight samples were analyzed for nitroglycerin, DNTs, TOC, pH, and CEC. Summary statistics for these soil samples collected at the SKT are provided in Table 5-4, and analytical results for target analytes detected at least once in shallow and deep surface soil are presented in Table 5-5.

Five metals (antimony, arsenic, cobalt, lead, and manganese) were detected in both shallow and deep surface soil samples at concentrations exceeding Maine RAGs and USEPA RSLs (with the exception of

manganese which only exceeded in shallow surface soil). Figure 5-2 shows the positive detection in soil. Cadmium was detected at concentrations exceeding only the Maine RAG and aluminum, chromium, and iron were detected at concentrations that exceeded only USEPA RSLs. Antimony and arsenic were detected at concentrations that exceeded Maine RAGS by two orders of magnitude and USEPA RSLs by three orders of magnitude. All concentrations of aluminum, cadmium, cobalt, and manganese were an order of magnitude or less greater than screening levels. All metals concentrations that exceeded the screening levels by more than one order of magnitude were detected in the uppermost surface samples (0 to 3 inches).

Figure 5-3 shows the positive detections of PAHs, nitroglycerin, and DNTs. Nitroglycerin and DNTs were either not detected or were detected at concentrations less than screening levels in all of the soil samples. Several PAHs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were detected at concentrations that exceeded both Maine RAGS and USEPA RSL by an order of magnitude or more. Concentrations of PAHs that exceeded screening levels by more than one order of magnitude were from uppermost surface soil samples collected from 0 to 3 inches.

5.4.2.2 Sediment

Four sediment samples were collected and analyzed for TAL metals and TOC. Summary statistics for these sediment samples are provided in Table 5-6, and analytical results for target analytes detected at least once in sediment are presented in Table 5-7. Figure 5-4 shows sediment positive detections.

Several metals (aluminum, antimony, arsenic, barium, beryllium, chromium, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, vanadium, and zinc) were detected in sediment samples at concentrations exceeding PALs. All metals were detected at concentrations exceeding PALs by an order of magnitude or less with the exception of manganese. Maximum concentrations of all metals were detected in sediment samples (NASB-SKT-SD01, -SD02, and -SD03) located within the central portion of the Lower Impoundment Pond.

5.4.2.3 Surface Water

Four surface water samples were collected and analyzed for TAL metals. Summary statistics for these surface water samples are provided in Table 5-8, and analytical results for target analytes detected at least once in surface water are presented in Table 5-9. Figure 5-4 shows surface water positive detections.

Aluminum, barium, cadmium, iron, lead, and manganese concentrations exceeded PALs in surface water by an order of magnitude or less. The maximum concentrations of barium, cadmium, and manganese were detected at sample NASB-SKT-SW01. The maximum concentrations of aluminum and lead were detected in sample NASB-SKT-SW03 and the maximum concentration of iron was detected in sample NASB-SKT-SW02.

5.4.2.4 Data Usability

Data usability was evaluated based on the results of data validation and the DQR, which are discussed in Appendix E. Based on the DQR for the SKT, SI data are of acceptable quality to make decisions on the path forward for the site. The following summarizes the evaluation for the individual DQIs for SKT analytical results:

- Validation process - In accordance with the UFP-SAP, full data validation was conducted. Based on the validation results, no data collected for SKT were rejected.
- Completeness - Sample collection completeness for all sample types was at least 100 percent. The sample analytical completeness for all sample types was also at least 100 percent.
- Sensitivity - All of the non-detected nitroglycerin soil results and silver surface water results were greater than corresponding screening criteria. Sensitivity for all other analytes and matrices was sufficient for the purposes of this investigation.
- Laboratory Accuracy - There were no significant laboratory accuracy concerns for SKT samples. See Appendix E for discussions on site data qualified due to laboratory accuracy issues and corresponding result biases if any.
- Precision - No significant QC deficiencies were noted. See Appendix E for discussions on site data qualified due to precision issues.
- Comparability - No comparability issues were noted.
- Representativeness - The reported data are adequately representative of site conditions and intended populations at SKT.

5.5 CONCLUSIONS

5.5.1 Shallow and Deep Surface Soil

For shallow and deep surface soil, a total of 14 chemicals (aluminum, antimony, arsenic, cadmium, chromium, cobalt, iron, lead, manganese, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene) were detected at concentrations exceeding screening levels. All other analytes were detected at concentrations less than screening levels.

5.5.2 Sediment

Seventeen metals (aluminum, antimony, arsenic, barium, beryllium, chromium, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, vanadium, and zinc) were detected in sediment samples at concentrations exceeding PALs. Maximum concentrations of all metals were detected in sediment samples located within the Lower Impoundment Pond.

5.5.3 Surface Water

Aluminum, barium, cadmium, iron, lead, and manganese concentrations exceeded PALs in surface water by an order of magnitude or less. The maximum concentrations of these metals were in samples collected from the Lower Impoundment Pond.

5.6 UPDATED CONCEPTUAL SITE MODEL

A CSM describing the SKT and its environmental setting was established in the PA Report (2006). The CSM has been updated based on the findings of this SI and is summarized in Table 5-19. Exposure pathways by which site receptors could be exposed to or contaminated by MC are shown on Figure 5-5, and Figure 5-6 presents a graphical representation of the CSM.

5.7 RECOMMENDATIONS

Further characterization of shallow surface soil is recommended for the SKT.

Soil: Shallow surface soil (0 to 3 inches bgs) is contaminated with metals and PAHs (primarily antimony, arsenic, lead, and benzo(a)pyrene) at unacceptable concentrations. The contamination appears to be located within the combined middle area of the pre-1950 and post-1950 range fans overlap. Contamination is present from the firing points extending outward to encompass the shotfall zones in this central area. Additional shallow surface soil sampling to refine the area is recommended.

Analytes for further sampling should include antimony, arsenic, lead, and select PAHs.

Groundwater: Groundwater was not investigated, pending evaluation of soil results. Because only shallow surface soils (0 to 3 inches bgs) are of primary concern, it does not appear that contamination has migrated to deeper soils at concentrations of concern and, therefore, the migration pathway from soil to groundwater is not complete. Therefore, for groundwater no investigation is warranted.

Surface Water: Metals were detected at elevated concentrations in surface water. Further assessment is recommended for the site pond.

Sediment: Metals were detected at elevated concentrations in sediment. Further assessment is recommended for the site pond.

X = Indicates sample was collected and analyzed as proposed in the Uniform Federal Policy Sampling and Analysis Plan (UFP-SAP) (Tetra Tech, 2009)

bgs = Below ground surface.

PS = Polyethylene scoop.

SS = Surface soil.

CEC = Cation exchange capacity.

SPLP = Synthetic precipitation leaching procedure .

SB = Soil

FBL = Fixed-base laboratory.

TOC = Total organic carbon.

SKT = Skeet Range.

HA = Hand auger.

XRF = X-ray fluorescence.

PD = Ponar Dredge.

NASB-SKT-SW04	4/9/2010	815	4.0/2.5	5.0	Kemmler/ Composite	Clear	5.69	169	10.44	4.93	8.76	0.08	240.4	Collected composite sample from 4 ft bgs and 2.5 ft bgs.

°C = Degrees Centigrade.

mg/l = Milligrams per liter.

mS/cm = Millisiemens per centimeter.

mV = Millivolts.

DO = Dissolved oxygen.

NTU = Nephelometric turbidity unit.

ft bgs = Feet below ground surface.

ORP = Oxidation/reduction potential.

Standard Values:

NIST 2709 = 18.9 ppm

NIST 2710 = 5532 ppm

QA = Quality Assurance

(1) Predicted laboratory concentrations were not calculated for those XRF values greater than 100 mg/kg.

N/A = Not Applicable.

in-bgs = Inches below ground surface.

BKG = Background sample.

PPM = Parts per million.

Bolded - Average soil sample value exceeds 340 ppm (MEDEP Residential Guideline, January 13, 2010).

Pb = Lead.

MEQ/100 = Milliequivalent.

S.U. = Standard Unit.

mg/kg = Milligrams per kilogram.

ug/kg = Micrograms per kilogram.

XRF = X-ray fluorescence.

J = Value is estimated.

NC = No criteria.

Yellow Shading - concentration greater than Maine RAGS criterion.

Italics - concentration greater than RSL criterion.

1 Maine RAGS, Appendix 3, (Jan, 2010).

2 USEPA residential Regional Screening Level

(June, 2011). Non-carcinogen values are divided by 10.

3 Minimum and maximum non-detections are for all samples in the data set.

Note: Chromium screening levels are for hexavalent chromium.

Note that a sample and its duplicate sample were considered separately when determining the maximum concentration, and the average concentration of a sample and its duplicate were used in determining frequency of detection.

MEQ/100 = Milliequivalent.

NC = No criterion.

J = Value is estimated.

S.U. = Standard Units.

U = Analyte not detected at the reported detection limit.

Yellow Shading - concentration greater than Maine RAGs criterion.

Italics - concentration greater than RSL criterion.

Note: Chromium screening levels are for hexavalent chromium.

1 Maine RAGS, Appendix 3, (Jan, 2010).

2 USEPA residential Regional Screening Level (June, 2011). Non-carcinogen values are divided by 10.

TABLE 5-10
CONCEPTUAL SITE MODEL INFORMATION PROFILE
SKEET RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK MAINE
PAGE 1 OF 3

Profile Type	Information Needs	Findings
Range/Site Profile	Installation Name	Former Naval Air Station Brunswick
	Installation Location	Cumberland County, Maine
	Range/Site Name	Skeet Range
	Range/Site Location	Located Approximately 75 meters north and 100 meters east of the current Building 55 and adjacent to the Machine Gun Boresight Range.
	Range/Site History	Shown on installation maps from 1946 and in an aerial photo from 1957.
	Range/Site Area and Layout	The Skeet Range encompasses approximately 73.2 acres. On the map from 1946, the range is shown with the firing towards the north; however, in the 1957 aerial photo and on later maps, the range is shown firing to the east.
	Range/Site Structures	Aerial photos show shot house for skeet; however, structures that existed when the range was active are no longer present at the site.
	Range/Site Boundaries	N: Building 211 S: Forested Area E: Forested Area W: Orion Street
	Range/Site Security	No security or access restrictions to the site.
Munitions/Release Profile	Munitions Types	Shotgun ammunition – 12 Gauge.
	Maximum Probability Penetration Depth	Small arms, one foot or less. Based on the SI results, contamination presenting a concern is located primarily in the top 3 inches (shallow surface soil) of the ground surface.
	MEC Density	Not applicable.
	Munitions Scrap/ Fragments/ MDAS	Not applicable.
	Associated MC	Primary MC is lead (associated with bullets), as confirmed by the SI. Other associated MC included: antimony (increases hardness), arsenic (present in lead), and PAHs (associated with skeet clay targets).

TABLE 5-10
CONCEPTUAL SITE MODEL INFORMATION PROFILE
SKEET RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK MAINE
PAGE 2 OF 3

Profile Type	Information Needs	Findings
	Migration Routes/Release Mechanisms	Erosion – The majority of the Skeet Range is level. A drainage is present south of Neptune Drive within the Skeet Range. The drainage is a natural feature and well vegetated, therefore, no significant run-off is anticipated from the Skeet Range. Run-off that does occur will flow into the retention ponds, which retain the majority of the surface water from this area for collection and reduction of suspended sediment. Contamination from runoff is not significant based on acceptable risk evaluation of detention pond sediment and surface water. Moreover, significant migration of contamination from the shallow surface to the deep surface soils is not evident.
Physical Profile (see Section 2)	Climate	Continental climate with three well-defined seasons. Highest temperatures occur in July (79F or higher). Coldest temperatures occur in January (21F or lower).
	Topography	The majority of the Skeet Range is level. A northwest-southeast trending drainage is present south of Neptune Drive within the Skeet Range.
	Geology	Silty Clay with occasional fine sand, trace small fragments, wet soft, very soft, corresponds to the descriptions of the Presumpscot Formation.
	Soil	Soils from the Suffield-Buxton-Hollis Association which consists of deep to shallow, moderately well drained to somewhat poorly drained soils that are characterized by low permeability. The field boring log for monitoring well 078 lists the top soil as dark brown, fine sandy silt with black, silty, fine sand just below the topsoil. From 0.1 to 5 feet bgs the soil is reddish bring to tan moist loose sand.
	Hydrogeology	The yield of bedrock wells in the vicinity of the NASB ranges from less than 10gpm to over 50gpm. Most of the wells in the vicinity are between 101 and 300ft deep.
	Hydrology	Surface water flows towards the retention ponds which are a part of the Merriconeag Stream watershed.
	Vegetation	The majority of the Skeet Range (post 1950) area is open and grassy with carious crops of woodland species of trees (mostly pine). The Skeet Range (pre1950) is highly developed and vegetation consists mainly of urban landscaping and small trees.
Land Use and Exposure Profile	Current Land Use	The area is primarily undeveloped except for the northernmost portion, which contains a baseball field and is intersected by Neptune Drive.
	Current Human Receptors	Current human receptors include: Civilian, visitors, trespassers, and maintenance workers/contractors.
	Current Activities	Grounds crew and pedestrian traffic.

TABLE 5-10
CONCEPTUAL SITE MODEL INFORMATION PROFILE
SKEET RANGE
FORMER NAVAL AIR STATION BRUNSWICK
BRUNSWICK MAINE
PAGE 3 OF 3

Profile Type	Information Needs	Findings
	Potential Future Land Use	Potential future land use included Community Mixed Use, Recreation, and Business and Technology.
	Potential Future Human Receptors	Potential future human receptors include residents, workers, visitors, trespassers, maintenance workers, and contractors.
	Potential Future Land Use Related Activities	Potential future land use related activities include business and technology related industry, residential, outdoor recreation, retail, offices, and day care.
	Zoning/Land Use Restrictions	No site specific restrictions or access controls exist for the Skeet Range. However, a portion of Site 9 lies within the Skeet Range site boundary and Site 9 has soil and groundwater restrictions. Additionally, the Eastern Plume, which has groundwater restrictions, extends into the Skeet Range
	Demographics/Zoning	Cumberland County population density is approximately 50,000 persons per square mile.
	Beneficial Resources	Groundwater is the source of the municipal water supply. However, the wells are screened in the deep aquifer (>100 feet below surface).
Ecological Profile	Habitat Type	Scrub/shrub, open field, forested areas, and an open water wetland (retention ponds).
	Degree of Disturbance	Limited to surface activities including grounds maintenance.
	Ecological Receptors and Species of Special Concern	Potential ecological receptors include indigenous species. The state-listed Blanding's turtle and spotted turtle (threatened) may reside in wetlands, vernal pools, or streams on or near the former installation.
General Exposure Profile	Relationship of MC Sources to Habitat and Potential Receptors	MEC not suspected at this site. MC potential migration pathways include infiltration to subsurface soil, infiltration and leaching to groundwater, and to a lesser extent dust emissions and volatilization to ambient air. Future planned land use includes Community Mixed Use, Recreation, and Business and Technology

NASB = Naval Air Station Brunswick.

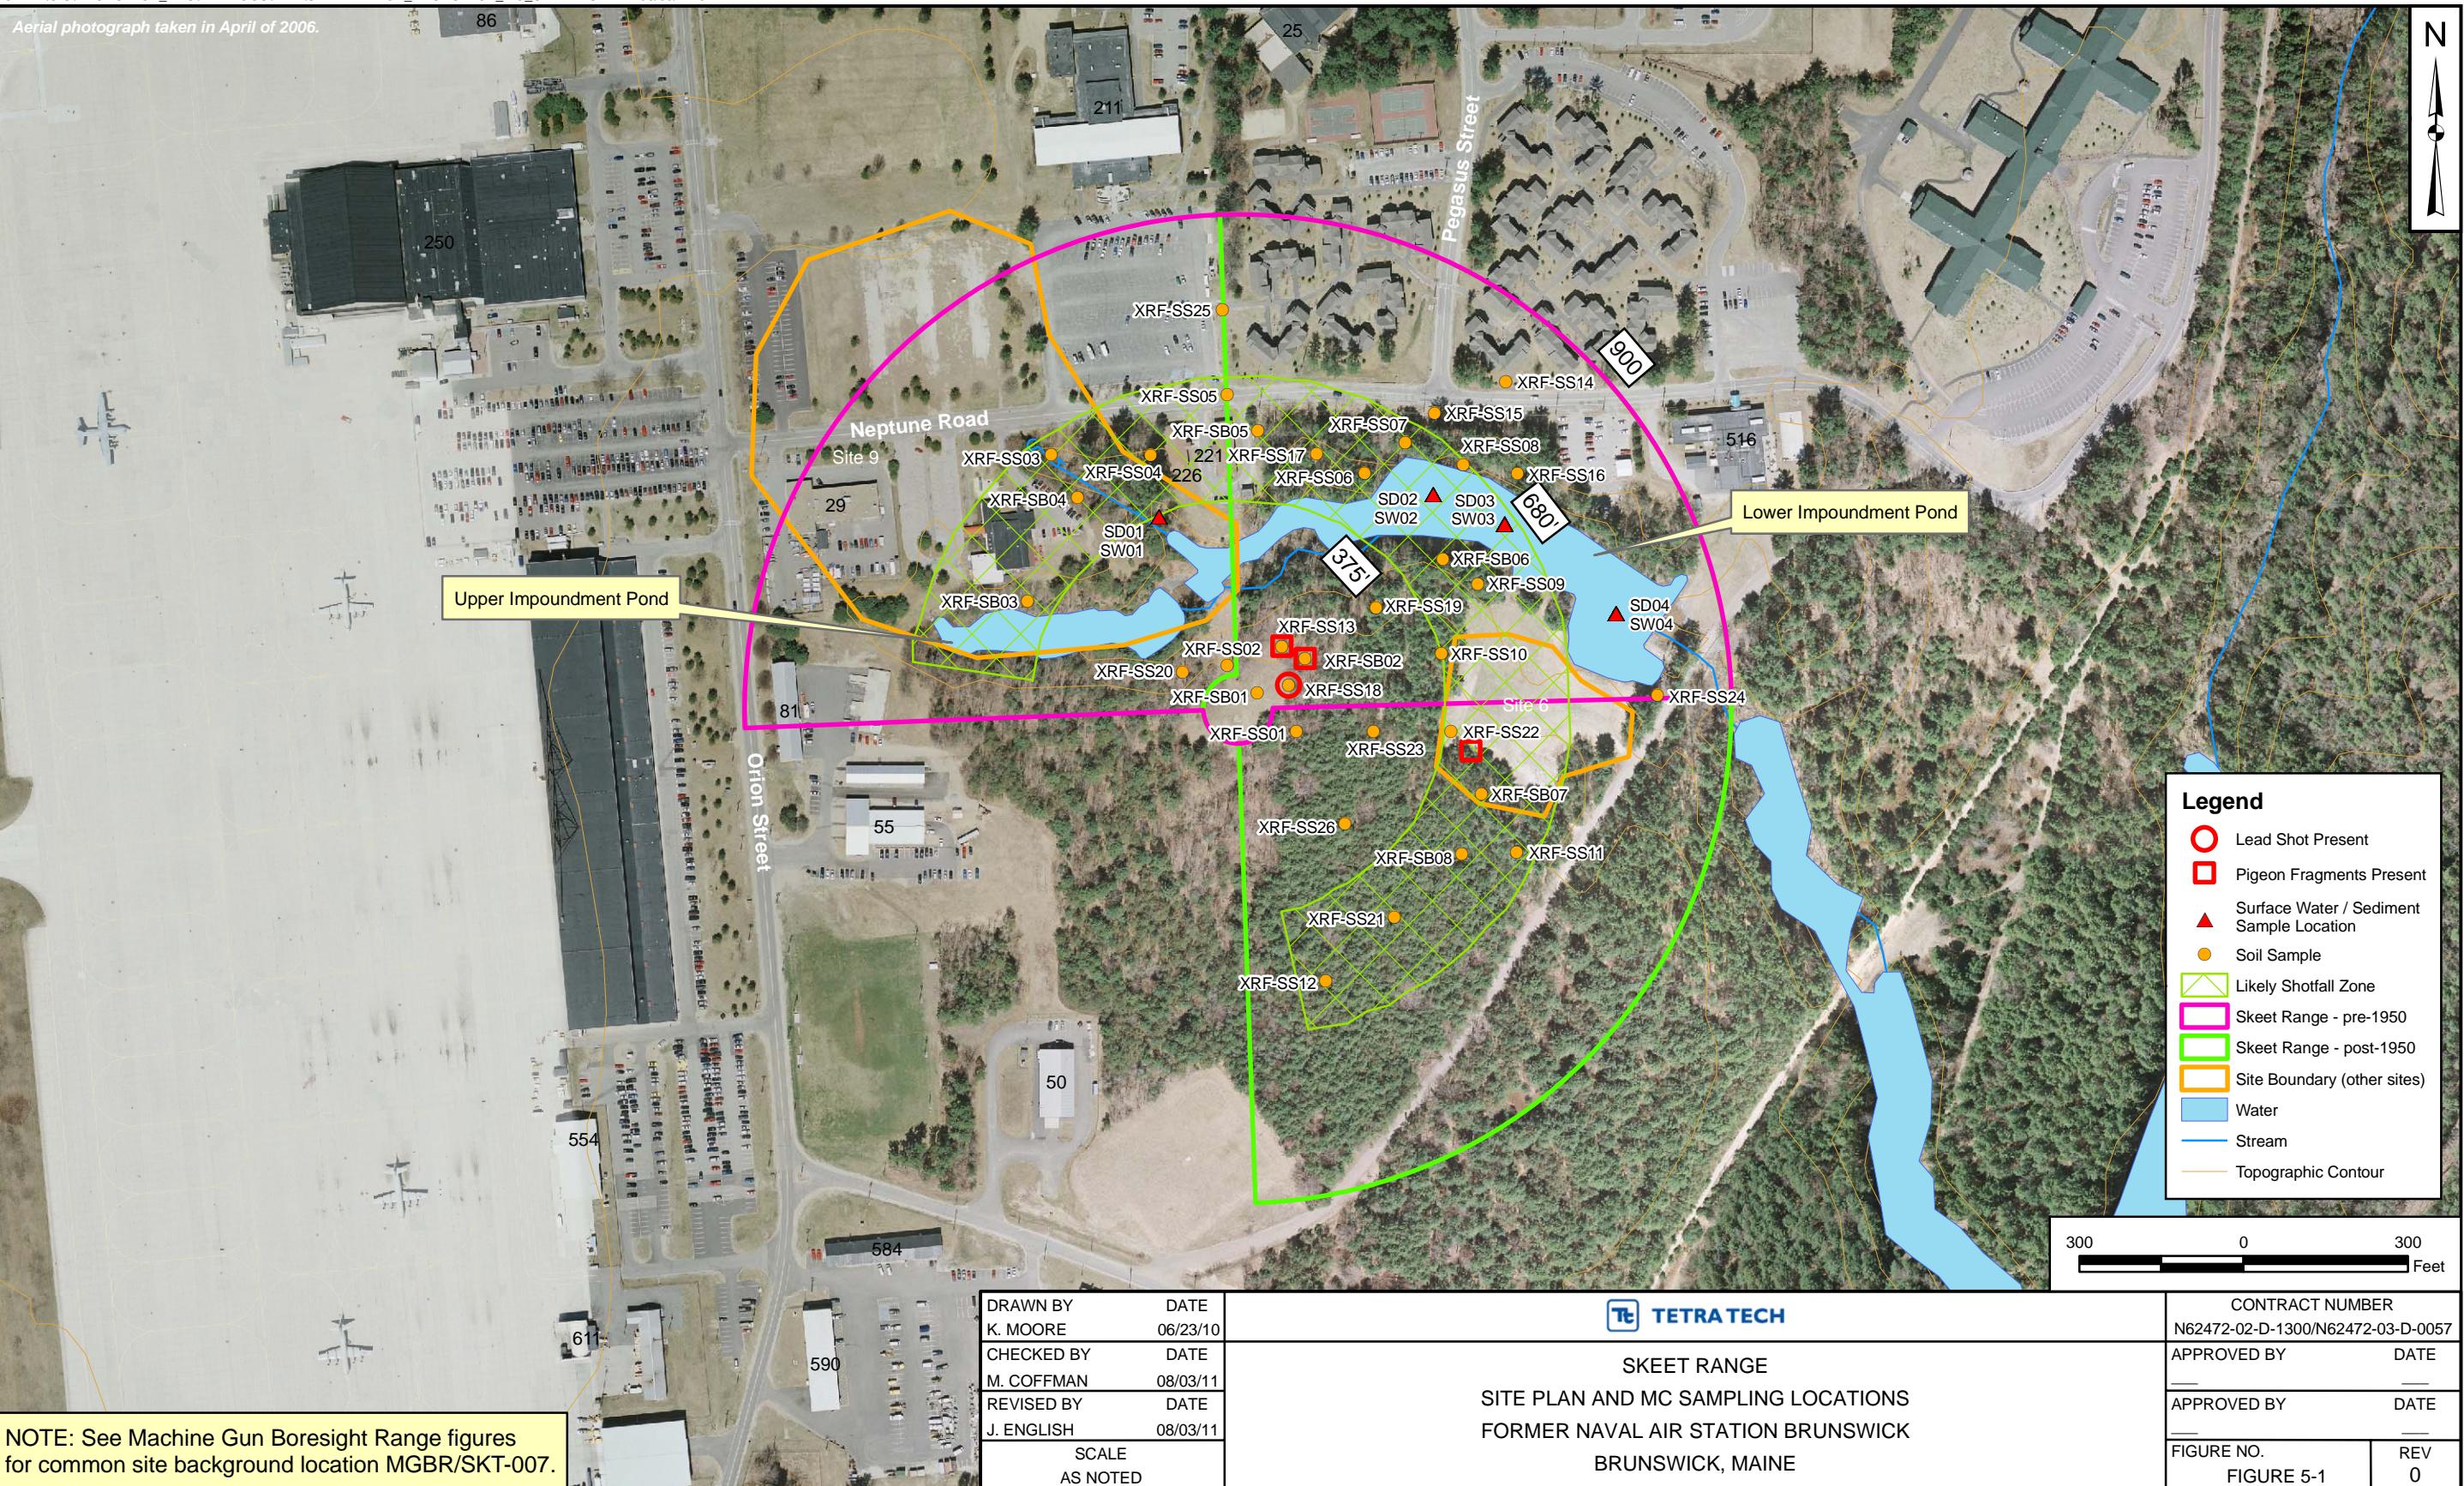

MEC = Munitions and explosives of concern.

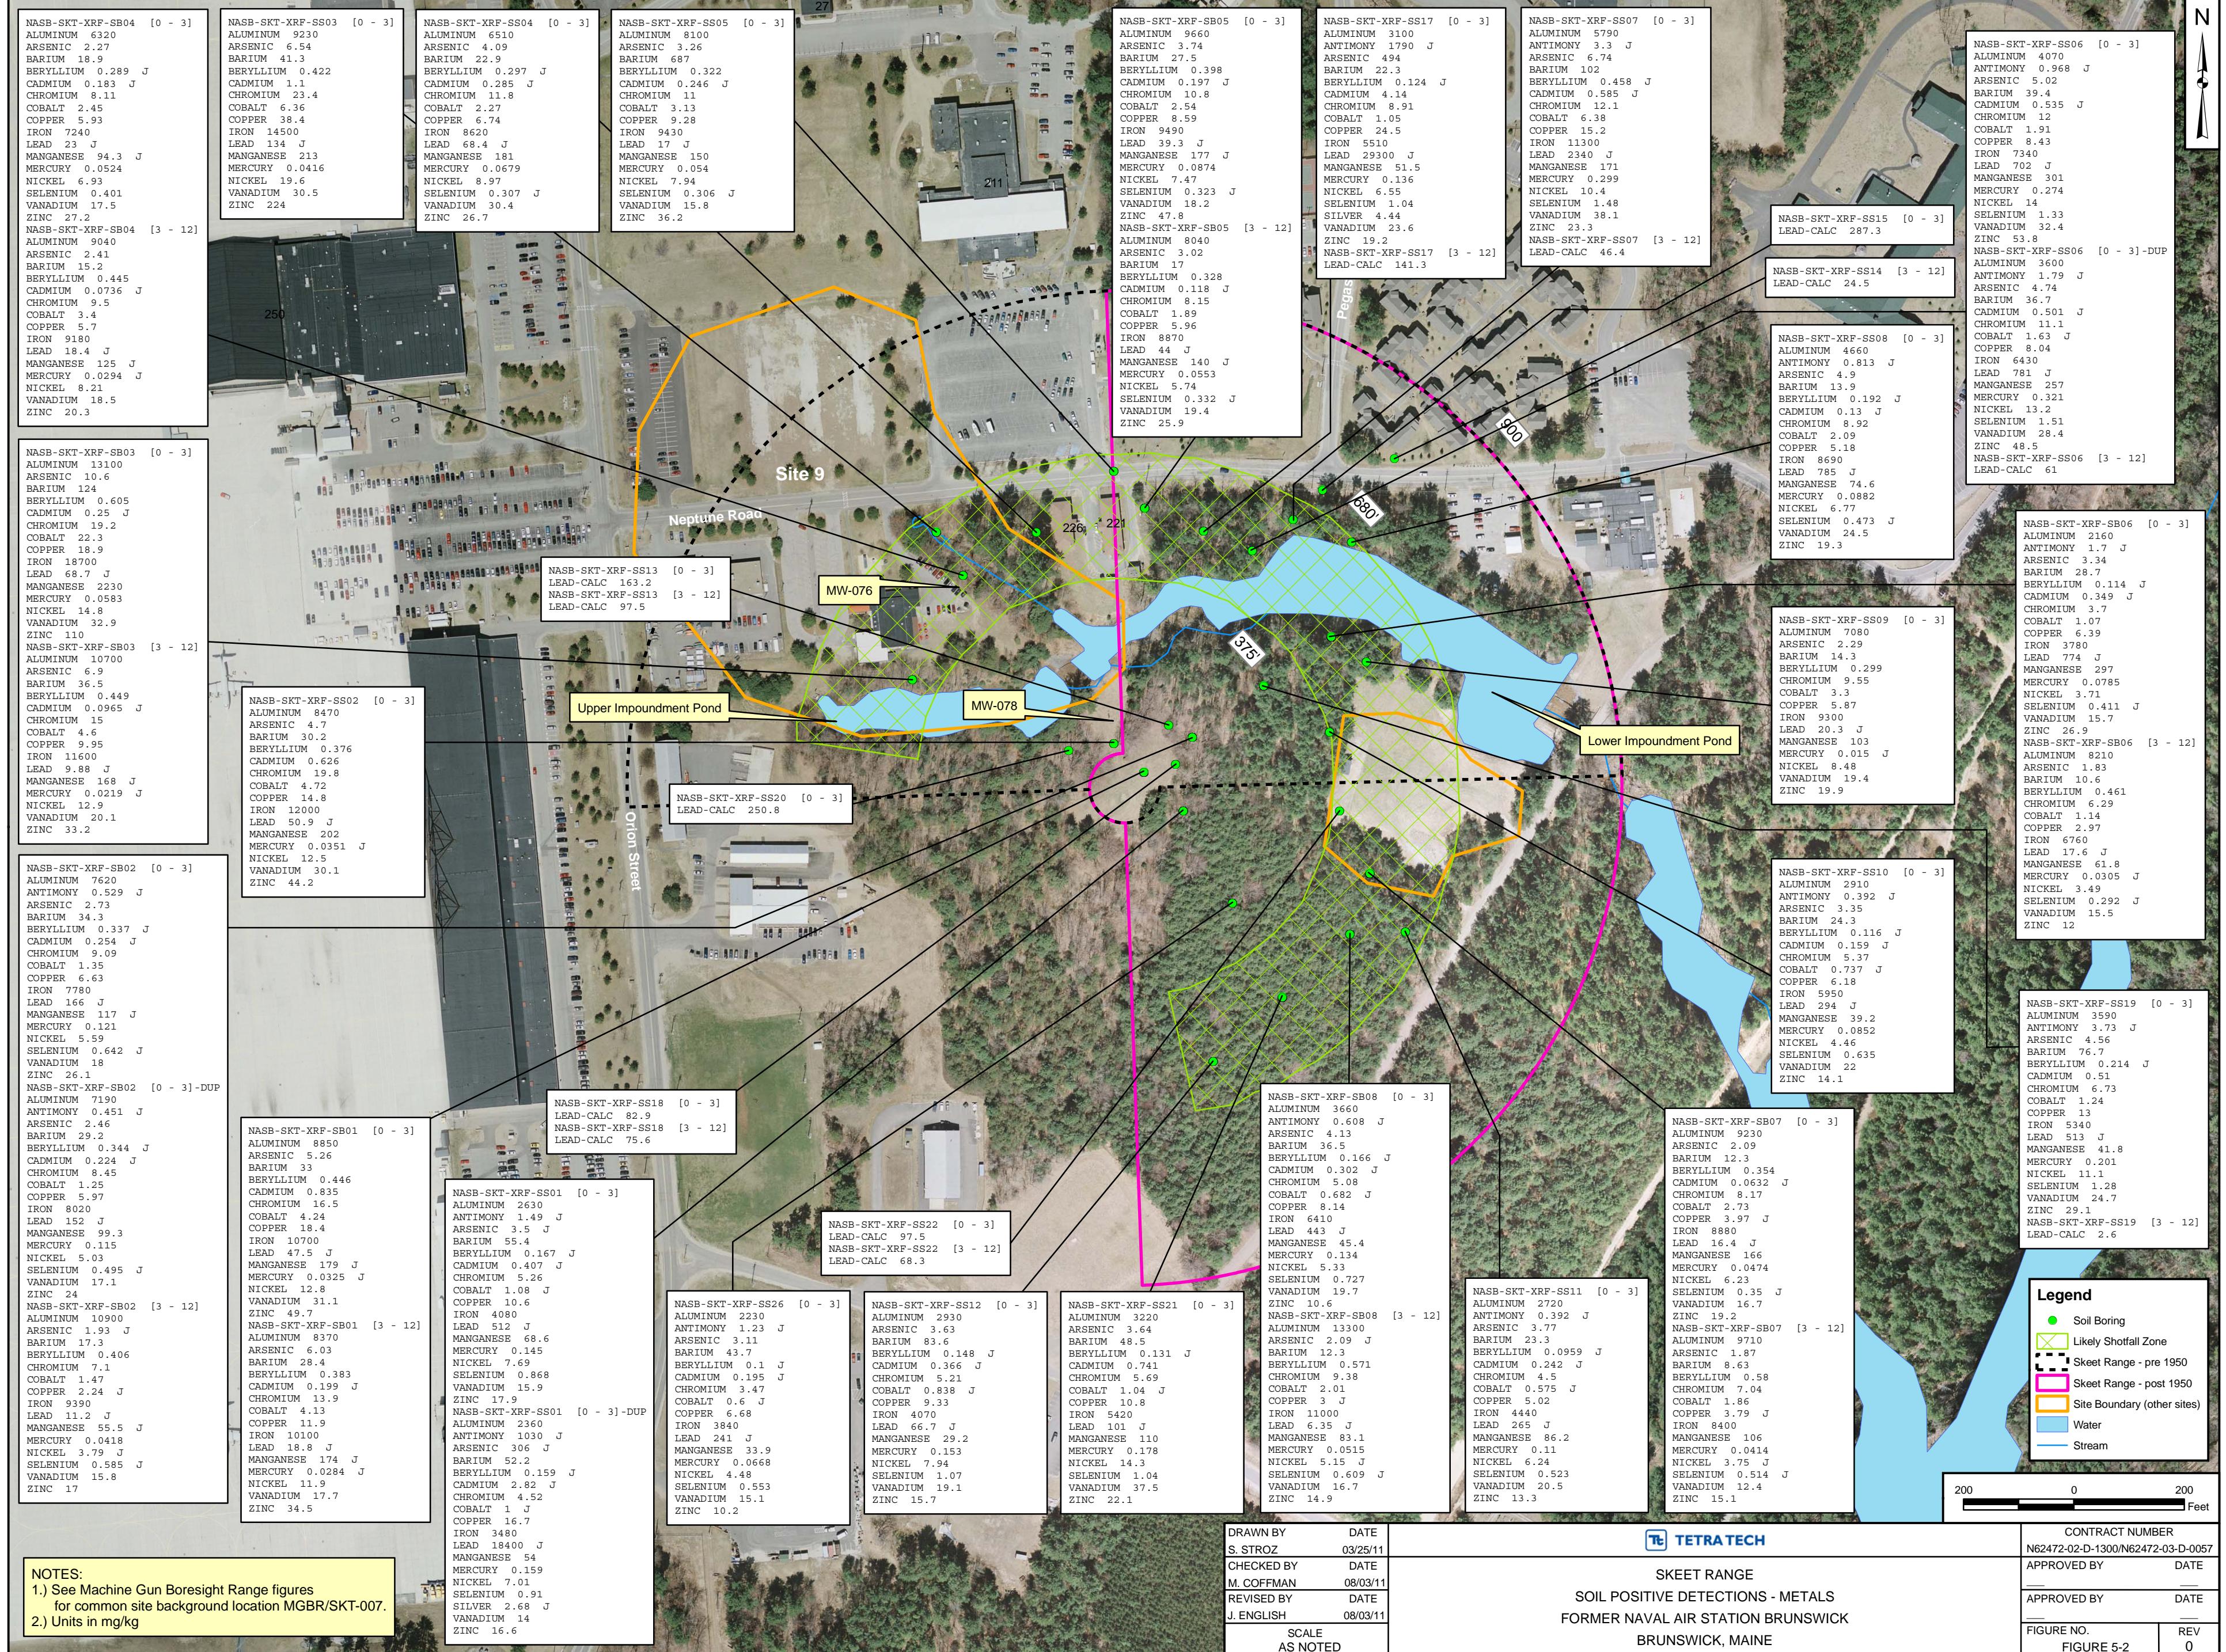

MC = Munitions constituent.

MDAS = Material documented as safe.

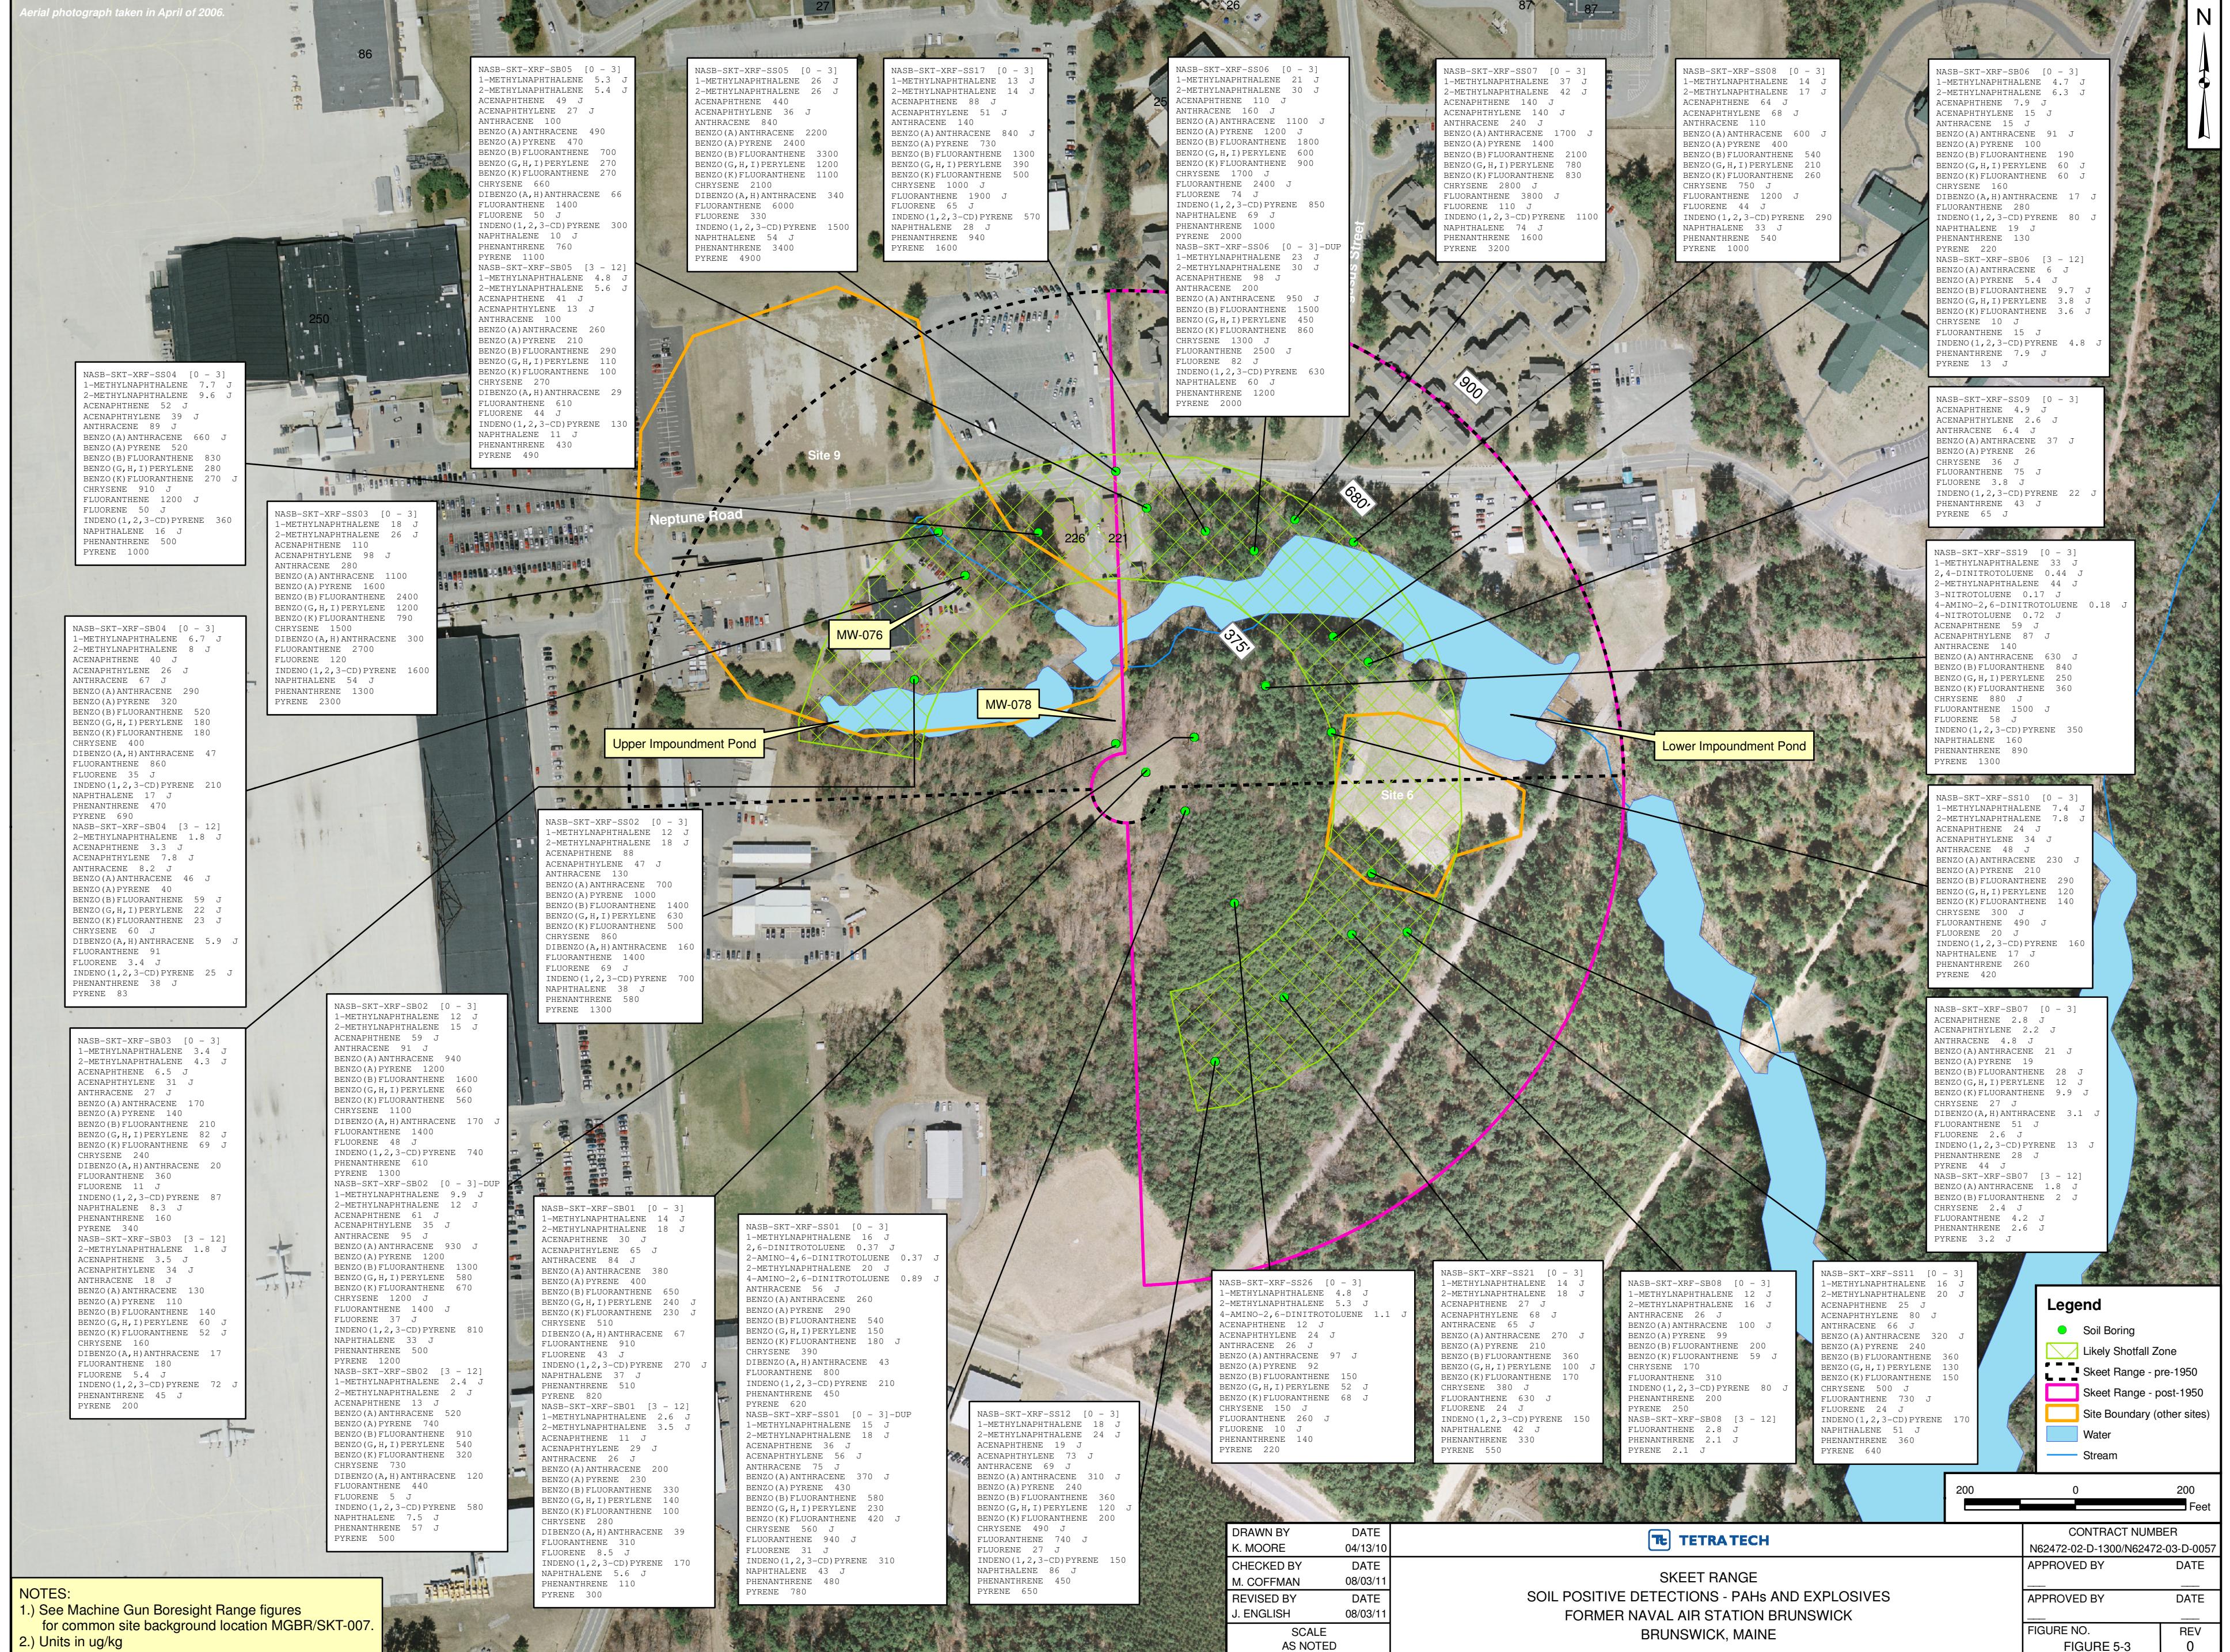

Bgs = Below ground surface.

SI = Site Investigation.

Data Recorded By: CFS Signature: C.Felt

Notes: WL measuring pt = top of riser (TOB)

LNAPL signal at start (YES NO)

Weather: Cloudy Wind 10-20's

Tetra Tech NUS Charge No. 112G00645 0000.0505

QC: MA

(If applicable)

H&S Survey Meter 0.0 PPM

Pre-pump insertion WL _____ ft

Dedicated Tubing

Analysis (LAB)

Field Instrument Group A/B/C/D

Post - pump insertion WL 5.31 ft

TAL Metals

Acetone
Nitrobenzene

Psychiatre

(Also see separate logsheet for gw)

1. Pump dial setting (for example: hertz, cycle/min, etc.)
 2. Siemens per cm (same as umhos/cm) at 25 °C.
 3. Oxidation reduction potential (stand in for Eh).

TETRA TECH NUS, INC.

SAMPLE LOG SHEET - "LOW FLOW" GROUNDWATER

Site Name: NASB – Machine Gun Boresight Range

Sample ID: **NASB-MGBR-MW02 - 122909**

Sample Method: Low Flow (stress) with Peristaltic Pump

Depth Sampled: 9 Feet Screened Interval Depth 4-14 feet

Sample Date & Time: 12/29/2009 0950 hours yes /Dup

Sampler(s): B.Geringer, C. Fellows

Data Recorded By: B. Geringer Signature: B. Geringer
Notes: WL measuring pt = top of rear (TOP) yes

Notes: WL measuring pt = top of riser (TOR) yes

LNAPL signal at start (YES/NO) **No**

Weather: Cloudy / cold / very Windy

Tetra Tech NUS Charge No. 112G00645 0000.0505

QC: **NASB-MGSR-Gw-Dvpoj - 122909** (If applicable)

APPENDIX E

MC DATA USABILITY ASSESSMENT

APPENDIX E

ANALYTICAL DATA QUALITY REVIEW
SITE INSPECTION
MUNITION CONSTITUENTS AT TWO MUNITIONS RESPONSE SITES
NAS BRUNSWICK, BRUNSWICK, MAINE

A description of the data review processes used to determine whether analytical laboratory data were of acceptable technical quality for use in decision making is presented in this data quality review (DQR). The review began with data verification and validation. Verification is a process used to ensure that contractual requirements were satisfied. Validation is a comparison of data quality indicators (DQIs) against prescribed acceptance criteria to assess analytical method performance. The DQIs used are measures to assess the bias and precision of the analytical calibrations and sample analyses. Together, verification and validation are the first steps in evaluating data completeness, accuracy, sensitivity, comparability, and representativeness. The data review process culminates with a data usability assessment during which the final usability of the data is established relative to the intended data use.

1.0 DATA VALIDATION PROCESS

All of the results from analytical laboratory samples were validated according to several specifications. Assignment of data qualification flags conformed to rules established in USEPA Region 1 Laboratory Data Validation Functional Guidelines for Evaluating Organic Analyses – Part II (December 1996), USEPA Region I Laboratory Data Validation Functional Guidelines for Evaluating Inorganic Analyses (November 2008), and Department of Defense (DoD) document entitled Quality Systems Manual (QSM) for Environmental Laboratories (April 2009) to the greatest extent practicable for non-contract laboratory program data. Numerical criteria used in conjunction with these rules were specified in the Quality Assurance Project Plan for Site Inspection of Munitions Constituents, Three Munitions Response Site, NAS Brunswick, Brunswick, Maine which is Attachment 1 of Appendix 1 within the document titled Site Inspection Work Plan, Munitions Constituents at Three Munitions Response Sites, NAS Brunswick, Brunswick, Maine (Tetra Tech, June 2009).

If no qualifier is assigned to a result that has been validated, the data user is assured that no analytical performance deficiencies were identified during validation. The qualification flags used are defined below:

U – Indicates that the chemical was not detected at the numerical detection limit noted. Non-detected results are reported with a “U” qualifier when received from the laboratory. Additionally, a “U” qualifier is added to a result (reported by the laboratory) if the detected concentration is determined to be attributable to contamination introduced during field sampling or laboratory analysis.

UJ – Indicates that the chemical was not detected. However, the detection limit (sample-specific quantitation limit) is considered to be estimated based on problems encountered during laboratory analysis. The associated numerical detection limit is regarded as inaccurate.

J – Indicates that the chemical was detected. However, the associated numerical result is not an accurate representation of the amount that is actually present in the sample. The laboratory reported concentration is considered to be an estimate of the true concentration.

UR – Indicates that the chemical may or may not be present. The non-detected analytical result reported by the laboratory is considered to be unreliable and unusable. The “UR” qualifier is applied in cases of gross technical deficiencies (i.e., holding times missed by a factor of two times the specified time limit, severe calibration noncompliances, and extremely low quality control [QC] recoveries).

R – Indicates that the chemical may or may not be present. The analytical result reported by the laboratory is considered to be unreliable and unusable. The “R” qualifier is applied in cases of gross technical deficiencies (i.e., holding times missed by a factor of two times the specified time limit, severe calibration noncompliances, and extremely low QC recoveries).

The preceding data qualifiers may be categorized as indicative of major or minor problems. Major problems are defined as issues that result in the rejection of data and qualification with “UR” or “R” data validation qualifiers. Rejected data are considered invalid and are not used for decision making purposes unless used in a qualitative way and the use is justified and documented. Less severe deficiencies, associated with “U”, “J”, and “UJ” data validation qualifiers, are defined as issues resulting in the estimation of data. Estimated analytical results are considered to be suitable for decision-making purposes unless the data use requirements are very stringent and the qualifier indicates a deficiency that is incompatible with the intended data use. Also, a “U” qualifier does not necessarily indicate that a data deficiency exists because all non-detect values are flagged with the “U” qualifier regardless of whether a quality deficiency has been detected.

No data collected for the site inspection (SI) of munitions constituents at the two munitions response sites and evaluated during this DQR was qualified as rejected. Qualified data and the reason for qualification are presented in Tables E.1 to E.7. Any data impacts based on the results of the data evaluation are discussed in the remainder of this review.

2.0 DATA VALIDATION OUTPUTS

After laboratory data were validated, a list was developed of non-conformities requiring data qualifier flags that were used to alert the data user to inaccurate or imprecise data. For situations in which several QC criteria were out of specification, the data validator made professional judgments and or comments on the validity of the overall data package. The reviewer then prepared a technical memorandum presenting qualification of the data, if necessary, and the rationale for making such qualifications. The net result was a data package that had been carefully reviewed for its adherence to prescribed technical requirements. Data validators incorporated data qualifiers into the electronic database and submitted the information to the Tetra Tech NUS, Inc. (Tetra Tech) data management group. A complete printout of the data results with validation flags is presented in Appendix D of the SI Report. Pertinent quality estimates are summarized in a more quantitative format in the following sections.

3.0 GENERAL DATA QUALITY REVIEW

The DQR provided herein is designed to provide an overall quantitative measure of analytical performance not provided by data validation. The analytical performance quantitative evaluations are frequently analyte-specific and reflect deficiencies such as biases associated with the quantification of particular analytes in a particular sample matrix. The data user must be aware that different chemicals in the same analytical fraction (e.g. lead and copper in the metals fraction) may exhibit different degrees of quality.

3.1 Completeness

Completeness is a measure of the number of valid samples or measurements that are available relative to the number of samples or measurements that were intended to be generated. For this project, completeness was measured on two different bases: samples collected and laboratory measurements.

- Sample completeness was a measure of the usable samples collected as compared to those intended to be collected.
- Laboratory measurement completeness was a measure of the amount of usable, valid laboratory measurements per matrix obtained for each target analyte.

Usable, valid samples (or results) were those judged, after data assessment, to represent the sampling populations and to have not been disqualified for use through data validation or additional data review. Completeness was determined using the following equation:

$$\%C = \frac{V}{T} \times 100$$

where %C = percent completeness
V = number of samples (or results) determined to be valid
T = total number of planned samples (or results)

Completeness evaluations for the Machine Gun Boresight Range and the NAS Brunswick Skeet Range are tabulated in Tables E.8 and E.9. All completeness evaluations meet the completeness goal of 95 percent listed in the Quality Assurance Project Plan for Site Inspection of Munitions Constituents, Three Munitions Response Site, NAS Brunswick, Brunswick, Maine (Appendix A, Attachment 1, QAPP Worksheet #12).

3.2 Sensitivity

The detection limits (DLs) reported by the laboratory were generally less than the screening limits listed in Appendix G. Tables E.10 through E.14 list parameters per site and per matrix (aluminum, arsenic, beryllium, copper, and lead) for which the detection limit exceeded the corresponding project action limit (PAL) for one or more sample results. PALs consist of site background limits (as applicable), EPA limits, and Maine state limits. Those tables also display two different percentages: the percentage of non-detected results that exceeded the corresponding PAL when compared to the total number of non-detected results and the percentage of non-detected results that exceeded PALs when compared to the total number of results analyzed (positive and non-detected results). The percentage of non-detected results that exceeded PALs when comparing to the total number of non-detected results is used to evaluate the overall success of the laboratory achieving detection limits equal to or less than PALs. The percentage of non-detected results that exceeded PALs when comparing to the total number of results analyzed (positive and non-detected results) is used to evaluate the effect of sensitivity exceedances on the complete corresponding data set. Lists of parameters per site and matrix for which sensitivity issues were identified and corresponding effects on data usability are described below. For additional information on those sensitivity issues please refer to Table E.10 through E.14.

NAS Brunswick Skeet Range

Sediment – antimony, selenium, silver

Soil – nitroglycerin, benzo(a)pyrene, dibenzo(a,h)anthracene, thallium

Surface water – silver

Sediment

The PAL used to evaluate the sediment results was a facility background limit. One hundred percent (2 of 2) of the non-detected sediment antimony results were reported at a concentration greater than the corresponding facility background limit. The antimony DL was greater than the facility background limit which resulted in the exceedances. Fifty percent (1 of 2) of the non-detected sediment selenium results were reported at a concentration greater than the corresponding facility background limit. The selenium DL was elevated due to dilution which resulted in the exceedance of facility background limits. Sixty percent (3 of 5) of the non-detected sediment silver results were reported at a concentration greater than the corresponding facility background limit. The silver DL was elevated due to dilution or low percent solids resulting in the exceedance of the facility background limit.

Soil

The PALs used to evaluate the soil results were USEPA Residential RSL and Maine RAGS Appendix C. One hundred percent (9 of 9) of non-detected soil nitroglycerin results, one hundred percent (4 of 4) of non-detected soil benzo(a)pyrene results, ninety five percent (18 of 19) of non-detected soil dibenzo(a,h)anthracene, and one hundred percent (35 of 35) of the non-detected soil thallium results exceeded the USEPA Residential RSL. The nitroglycerin, benzo(a)pyrene, dibenzo(a,h)anthracene, and thallium MDLs were greater than the Residential RSL. Twenty five percent (1 of 4) of non-detected soil benzo(a)pyrene results and twenty one percent (18 of 19) of non-detected soil dibenzo(a,h)anthracene exceeded the Maine RAGS Appendix C. The benzo(a)pyrene and dibenzo(a,h)anthracene MDLs were elevated due to low percent soilds resulting the exceedance of the Maine RAGS.

Surface Water

The PAL used to evaluate the surface water results was a facility background limit. Sixty (3 of 5) percent of the non-detected surface water silver results were reported at a concentration greater than the corresponding facility background limit. The silver DL was greater than the facility background limit resulting in the exceedance.

Machine Gun Boresight Range

Soil –arsenic, cadmium, thallium, nitroglycerin, antimony, cobalt

Groundwater –Thallium, nitroglycerin, arsenic, chromium, cobalt

Soil

The PALs used to evaluate the soil results were USEPA Residential RSL and Maine RAGS Appendix C. One hundred percent (9 of 9) of non-detected soil arsenic results, twenty one percent (4 of 19) of non-detected soil cadmium results, and sixteen percent (6 of 37) of the non-detected soil thallium results

exceeded the Maine RAGS Appendix 3 limits. The arsenic, cadmium, and thallium DL was greater than the Maine RAGS limit resulting in the exceedance. One hundred percent (28 of 28) of non-detected soil nitroglycerin results, sixteen percent (6 of 36) non-detected soil antimony results, one hundred percent (6 of 6) of non-detected soil arsenic results, one hundred percent (1 of 1) of non-detected cobalt results, and one hundred percent (37 of 37) of the non-detected soil thallium results exceeded the USEPA Residential RSL. The nitroglycerin, antimony, arsenic, cobalt, and thallium DL was greater than the USEPA Residential RSL.

Groundwater

The PALs used to evaluate the groundwater results were USEPA Tapwater RSL and Maine MEG. One hundred percent (9 of 9) of non-detected groundwater thallium results exceeded the Maine MEG limits. The thallium DL was greater than the Maine MEG limit resulting in the exceedance. One hundred percent (6 of 6) of non-detected groundwater nitroglycerin results, one hundred percent (5 of 5) non-detected groundwater arsenic results, one hundred percent (4 of 4) of non-detected groundwater chromium results, one hundred percent (4 of 4) of non-detected cobalt results, and one hundred percent (6 of 6) of the non-detected groundwater thallium results exceeded the USEPA Tapwater RSL. The nitroglycerin, antimony, arsenic, cobalt, and thallium DL was greater than the USEPA Tapwater RSL.

3.3 Laboratory Accuracy

Accuracy in the laboratory was measured through the comparison of a spiked sample or Laboratory control sample/laboratory control sample duplicate (LCS/LCSD) result to a known or calculated value and is expressed as a percent recovery (%R). Accuracy was also assessed by monitoring the analytical recovery of select surrogate compounds and internal standard compounds added to samples that are analyzed by organic chromatographic methods, and the analytical recovery of calibration standards for all analyses. LCSs were used to assess the accuracy of laboratory operations with minimal sample matrix effects. Matrix spike/matrix spike duplicate (MS/MSD) and surrogate compound analyses measure the combined accuracy effects of the sample matrix, sample preparation, and sample measurement. LCS and MS analyses were performed at a frequency of one per 20 associated samples of like matrix. Laboratory accuracy was assessed by comparing calculated percent recovery (%R) values to accuracy control limits specified by the laboratory using the appropriate SW-846 Method.

Percent recovery is calculated using the following equation:

$$\%R = \frac{S_s - S_o}{S} \times 100$$

where %R = percent recovery

Ss	=	result of spiked sample
So	=	result of non-spiked sample
S	=	concentration of spiked amount.

The inductively coupled plasma (ICP) Interference Check Sample (ICS) is evaluated to verify the laboratory's interelement and background correction factors, and to account for potential spectral overlaps and stray light interferences caused by the interfering analytes aluminum, calcium, iron, and magnesium. ICP ICS interference can affect the accuracy of analyte results and is therefore also evaluated in this section.

Following is an evaluation of qualified data (per site and per matrix) associated to accuracy data quality.

3.3.1 NAS Brunswick Skeet Range

Sediment: Antimony, barium, calcium, magnesium, and manganese results were qualified as estimated, (J), due to MS noncompliance. The MS/MSD analysis of sample NASB-SKT-SD01-0006 yielded a %R less than the lower QC limit for antimony and it also yielded %Rs greater than the upper QC limit for barium, calcium, magnesium, and manganese. Therefore the MS/MSD analysis of sample NASB-SKT-SD01-0006 indicates that antimony results qualified due to MS/MSD noncompliance are biased low and that barium, calcium, magnesium, and manganese results qualified due to MS/MSD noncompliance are biased high. Sediment data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, sediment data accuracy is considered acceptable. For more detailed information concerning qualified sediment data for the NAS Brunswick Skeet Range refer to Table E.1.

Soil: Acenaphthylene, anthracene, benzo(g,h,i)perylene, benzo(k)perylene, fluorene, indeno(1,2,3-CD)perylene, cation exchange capacity (CEC), lead, sodium results were qualified due to MS/MSD noncompliances that indicated those qualified data points are biased high. Antimony, magnesium, and potassium results were qualified due to MS/MSD noncompliances that indicated those qualified data points are biased low; however, no directional bias can be associated with those antimony results also qualified due to ICP noncompliance. Benzo(a)pyrene, chrysene, dibenzo(a,h)anthracene, fluoranthene, 2,4,6-trinitrotoluene, 2,4-dinitrotoluene, 2,6-dinitrotoluene, and 4-amino-2,6-dinitrotoluene results were qualified due to calibration noncompliance and no directional bias is associated with those noncompliances. Manganese and total organic carbon (TOC) results were qualified due to calibration noncompliances that indicated the corresponding qualified results were biased high and low, respectively. Arsenic data points were qualified due to ICP noncompliances that indicated the associated data points are biased high. Cobalt, nickel, selenium, and silver were qualified due to ICP noncompliances that indicated the associated

data points are biased low. Several antimony and cadmium data points were also qualified due to ICP noncompliance; however, no directional bias can be associated with those data points because those points were also qualified due to MS noncompliance. Soil data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, soil data accuracy is considered acceptable. For more detailed information concerning qualified soil data for the NAS Brunswick Skeet Range refer to Table E.2.

Surface Water: One magnesium result was qualified due to a calibration noncompliance that indicated the qualified data point in biased low. The magnesium surface water data non-compliance associated with accuracy was not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, surface water data accuracy is considered acceptable. For more detailed information concerning qualified surface water data for the NAS Brunswick Skeet Range refer to Table E.3.

3.3.2 Machine Gun Boresight Range

Soil: Silver results were qualified as estimated to due to blank spike contamination which indicated that those results were biased low. Calcium, magnesium, manganese, potassium, and sodium results were qualified due to MS noncompliances that indicated those qualified results were biased high. Antimony and lead results were qualified due to MS noncompliances that indicated those qualified results were biased low. Barium, selenium, manganese, and silver results were qualified due to calibration noncompliance. QC data indicated that the barium and selenium, and manganese and silver results were biased low and high, respectively. Antimony, arsenic, copper, nickel, selenium, and silver were qualified due to ICP interference noncompliance that indicated qualified arsenic results were biased high, and qualified copper, nickel, selenium, and silver results were biased low. No directional bias can be associated with the qualified antimony result because it was also qualified due to other QC noncompliances. The soil data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, soil data accuracy is considered acceptable. For more detailed information concerning qualified soil data for the Machine Gun Boresight Range refer to Table E.4.

Groundwater: Sodium results were qualified due to calibration noncompliance that indicated those qualified results were biased high and calcium results were qualified due to ICP serial dilution for which direction bias was indeterminate. The groundwater data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, groundwater data accuracy is considered acceptable. For more detailed

information concerning qualified groundwater data for the Machine Gun Boresight Range refer to Table E.5.

3.3.3 Background Samples

Soil: Antimony, calcium, lead, magnesium, and potassium were qualified due to MS noncompliance and QC data indicated that the qualified antimony and lead results were biased low and the qualified calcium, magnesium, and potassium results were biased high. Manganese, benzo(a)anthracene, chrysene, dibenzo(a,h)anthracene, and fluoranthene results were qualified due to calibration noncompliance. QC data indicated that the manganese background result qualified due to calibration noncompliance was biased high and direction bias of the organic compounds was indeterminate. One selenium and one silver background soil result were qualified due to ICP interferences which indicated that those results were biased low. A cadmium result was qualified due to ICP serial dilution compliance and the direction bias of that estimated result is indeterminate. The background soil data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, background soil data accuracy is considered acceptable. For more detailed information concerning qualified background soil data refer to Table E.6.

3.3.4 QC Samples

Rinsate blanks and Field Blanks: Nitroglycerin was qualified due to LCS noncompliance which indicated that the associated qualified results were biased low. Several organic compounds including 2,4,6-trinitrotoluene, 2,4-dinitrotoluene, 2,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, benzo(a)anthracene, benzo(g,h,i)perlyene, chrysene, dibenzo(a,h)anthracene, fluoranthene, and indeno(1,2,3-CD)pyrene were qualified due to calibration noncompliance for which direction bias was indeterminate. Chromium results were also qualified due to calibration noncompliance that indicated those qualified results were biased low. The QC data non-compliances associated with accuracy were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, QC data accuracy is considered acceptable. For more detailed information concerning qualified QC data refer to Table E.7.

3.4 Laboratory Precision

Precision is a measure of the degree to which two or more measurements are in agreement and describes the reproducibility of measurements of the same parameter for samples analyzed under similar conditions.

Precision for chemical parameters is expressed as a Relative Percent Difference (RPD), which is defined as the ratio of the difference to the mean for the two values being evaluated. RPDs, typically expressed as percentages, are used to evaluate both field and laboratory duplicate precision and are calculated as follows:

$$RPD = \frac{|V_1 - V_2|}{(V_1 + V_2)/2} \times 100$$

where RPD = relative percent difference
V₁, V₂ = two results obtained by analyzing duplicate samples

The precision estimates obtained from duplicate field samples encompass the combined uncertainty associated with sample collection, homogenization, splitting, handling, laboratory and field storage (as applicable), preparation for analysis, and analysis. In contrast, precision estimates obtained from analyzing duplicate laboratory samples incorporate only homogenization, sub sampling, preparation for analysis, laboratory storage (if applicable), and analysis uncertainties.

3.4.1 NAS Brunswick Skeet Range

Sediment: Beryllium, cadmium, mercury, and sodium results were qualified due to uncertainty near the detection limit. Positive results qualified due to uncertainty near the detection limit are considered imprecise; therefore qualified as estimated, because relative error increases as analyte concentrations approach corresponding IDLs. However, such non-compliances are not egregious enough to qualify the affected data as rejected according to data validation guidelines used for this project; therefore, data precision is not considered unacceptable due to those data points qualified because of uncertainty near the detection limit. For more detailed information concerning qualified sediment data for the NAS Brunswick Skeet Range refer to Table E.1.

Soil: Two explosives (4-nitrotoluene and 2-amino-4,6-dinitrotoluene) results were qualified due to percent difference (%D) noncompliance between gas chromatography (GC) columns indicating result imprecision. Arsenic, cadmium, silver, benzo(a)pyrene, benzo(k)fluoranthene, and dibenzo(a,h)anthracene results were qualified due to field duplicate imprecision. A thallium result was qualified due to percent solids less than 30% and many analytes (see Table E.2.) were qualified due to uncertainty near the detection limit. The soil data non-compliances associated with precision were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, soil data accuracy is considered acceptable. For more detailed information concerning qualified soil data for the NAS Brunswick Skeet Range refer to Table E.2.

Surface Water: Arsenic, cadmium, copper, lead, and nickel results were qualified due to uncertainty near the detection limit. Such non-compliances are not egregious enough to qualify the affected data as rejected according to data validation guidelines used for this project; therefore, data precision is not considered unacceptable due to those data points qualified because of uncertainty near the detection limit. For more detailed information concerning qualified surface water data for the NAS Brunswick Skeet Range refer to Table E.3.

3.4.2 Machine Gun Boresight Range

Soil: Beryllium, mercury, and nitroglycerin results were qualified as estimated due to uncertainty near the detection limit. Such non-compliances are not egregious enough to qualify the affected data as rejected according to data validation guidelines used for this project; therefore, data precision is not considered unacceptable due to those data points qualified because of uncertainty near the detection limit. For more detailed information concerning qualified soil data for the Machine Gun Boresight Range refer to Table E.4.

Groundwater: Aluminum and iron results were qualified due to field duplicate imprecision. Thirteen inorganic analytes (see Table E.5) were qualified due to uncertainty near the detection limit. The groundwater data non-compliances associated with precision were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, groundwater data accuracy is considered acceptable. For more detailed information concerning qualified groundwater data for the Machine Gun Boresight Range refer to Table E.5.

3.4.3 Background Samples

Soil: A arsenic and a lead result were qualified due to field duplicate imprecision, and eight analytes (see Table E.6) had results qualified due to uncertainty near the detection limit. The soil data non-compliances associated with precision were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, soil data accuracy is considered acceptable. For more detailed information concerning qualified background soil data refer Table E.6.

3.4.4 QC Samples

Rinsate blanks and Field Blanks: The 3-nitrotoluene and 4-nitrotoluene results for sample NASB-SKT-SO-RB01-121509 were qualified as estimated due to %D noncompliance between GC columns indicating result imprecision. Many organic and inorganic analyte results (see Table E.7) were qualified due to uncertainty near the detection limit. The QC data non-compliances associated with precision were not egregious enough to qualify the affected data as rejected according to the data validation guidelines used for this project; therefore, QC data accuracy is considered acceptable. For more detailed information concerning qualified QC data refer to Table E.7.

3.5 Comparability

Comparability is defined as the confidence with which one data set can be compared with another (e.g., among sampling points and among sampling events). Comparability was achieved by using standardized sampling and analysis methods, as well as standardized data reporting formats. Comparability of laboratory measurements was achieved primarily through the use and documentation of standard sampling and analytical methods. Results were reported in units that ensured comparability with previous data and with current state and federal standards and guidelines. Comparability of laboratory measurements was assessed primarily through the use of QC samples and through adherence to the quality assurance (QA) plan.

3.6 Representativeness

Representativeness is an expression of the degree to which data accurately and precisely depict the actual characteristics of a population or environmental condition existing at the site. By compiling with the Quality Assurance Project Plan for Site Inspection of Munitions Constituents, Three Munitions Response Site, NAS Brunswick, Brunswick, Maine which is Attachment 1 of Appendix 1 within the document titled Site Inspection Work Plan, Munitions Constituents at Three Munitions Response Sites, NAS Brunswick, Brunswick, Maine (Tetra Tech, June 2009), and the use of standardized sampling, sample handling, sample analysis, and data reporting procedures were designed so that the final data would be accurate representations of actual site conditions. The DQR found the data collected to be representative of targeted populations.

4.0 DATA USEABILITY

All data collected for this project is considered useable for the purposes of this project.

APPENDIX F

XRF/FBL CORRELATION STATISTICAL EVALUATION

F-1 MACHINE GUN BORESIGHT RANGE

F-2 SKEET RANGE

F-1 MACHINE GUN BORESIGHT RANGE

MGBR
Correlation of Fixed Based Laboratory and XRF Concentrations
Naval Air Station Brunswick, Maine

Five collocated XRF and fixed based laboratory concentrations were collected at MGBR Brunswick for lead, copper, nickel and zinc. To determine if the XRF concentrations can be used to predict the Fixed Based Laboratory concentrations a statistical correlation analysis was conducted. Due to the small sample size the correlation analysis will be strongly affected by any outliers and/or influential points. For the statistical analyses $\frac{1}{2}$ the detection limit was used for non-detected concentrations and for duplicate samples the average of the original and duplicate sample was used.

If the correlation between the XRF and Fixed Based Laboratory concentrations is greater than or equal to 0.65 then the XRF concentrations can be used to predict the fixed based laboratory concentrations. The correlation always falls between -1 and 1. Values of r near 0 indicate a very weak linear relationship. The strength of the linear relationship increases as r moves away from 0 toward either -1 or 1. Values of r close to -1 and 1 indicate that the points lie close to a straight line. The extreme values -1 and 1 occur only in the case of a perfect linear relationship. So the correlation indicates a strong linear trend. The R-squared value represents the percent of variation in laboratory concentrations that can be explained by the XRF concentration. An R-squared value greater than about 80 percent is considered to indicate a very strong relationship between the two measurement methods. The maximum possible value is 100 percent.

Figure 1 is a scatterplot of the XRF lead concentrations and the Laboratory lead concentrations for each sample. From the scatterplot, a linear trend is evident. The correlation is 0.97 indicating that there is a strong linear relationship between the XRF and laboratory concentrations. However, there is a wide range of concentrations with the XRF concentrations ranging from 49 mg/kg to 1640 mg/kg and the laboratory concentrations ranging from 57 mg/kg to 1000 mg/kg. However the maximum concentration appears to be a potential outlier. Figure 2 is a scatterplot of the XRF lead concentrations and the Laboratory lead concentrations with the potential outlier removed. From the scatterplot, a linear trend is evident. The correlation is 1 indicating that there is a strong linear relationship between the XRF and laboratory concentration. Table 1 presents the predicted laboratory concentrations for the XRF concentrations where no laboratory concentrations are available based on the regression equation with the potential outlier removed. For concentrations where the predicted laboratory concentration was negative, zero was used as the concentration.

Figure 3 is a scatterplot of the XRF copper concentrations and the Laboratory copper concentrations for each sample. From the scatterplot, there appears to be a linear trend for the four XRF concentrations less than 100 mg/kg. Note that the sample with an XRF concentration of 204 mg/kg is causing the regression line to have a slope close to zero. The correlation is -0.0074 indicating that there is a very weak linear relationship between the XRF and laboratory concentrations. Therefore, the XRF concentrations

will not be used to predict laboratory concentrations. Table 2 presents the XRF concentrations where no laboratory concentrations are available.

Figure 4 is a scatterplot of the XRF nickel concentrations and Laboratory nickel concentrations for each sample. From the scatterplot, there appears to be a linear trend for the XRF concentrations less than 100mg/kg. The two samples with XRF concentrations greater than 100 mg/kg are causing the regression line to have a slope close to zero. The correlation is -0.47, therefore the XRF concentrations will not be used to predict laboratory concentrations. Table 3 presents the XRF concentrations where no laboratory concentrations are available.

Figure 4 is a scatterplot of the XRF zinc concentrations and the Laboratory zinc concentrations for each sample. . From the scatterplot, a linear trend is evident. The correlation is 0.92 indicating that there is a strong linear relationship between the XRF and laboratory concentrations. However, there is a wide range of concentrations with the XRF concentrations ranging from 21U mg/kg to 245 mg/kg and the laboratory concentrations ranging from 20 mg/kg to 52 mg/kg. Table 4 presents the predicted laboratory concentrations for the XRF concentrations where no laboratory concentrations are available.

Subject: NAS Brunswick: Revised EPA data from EPA XRF Sampling @ Boresight Range
Attachments: Machine Gun Boresight Range XRF Pb Results.1 May 08.xls; 08050003metmsrev.pdf; Brunswick_Soil_Sampling_05012008.pdf

Hi Folks,

I'm forwarding to you a more complete set of data from EPA's XRF sampling effort at the Boresight Range SI site on 1 May. I asked our field and fixed lab folks to go back and provide me data for other metals that were analyzed besides lead. This data give a more complete picture of metals concentrations for the area that was sampled. I assume we will all delve back into MMRP SI MC (gotta love these acronyms) issues in the near future as a BCT.

Have a Happy 4th!

Mike

(See attached file: Machine Gun Boresight Range XRF Pb Results.1 May 08.xls)(See attached file: 08050003metmsrev.pdf)(See attached file: Brunswick_Soil_Sampling_05012008.pdf)

Laboratory Report

June 26, 2008

Michael Daly - HBT
US EPA New England, Region I
One Congress Street
Boston, MA 02114 - 2023

Project Number: 08050003

Project: Brunswick Naval Air Station - Brunswick, ME

Analysis: Metals in Soil Medium Level by ICP

EPA Chemist: Michael Dowling

MD 6/26/08

Analytical Procedure:

All samples were received and logged in by the laboratory according to the USEPA New England Laboratory SOP for Sample Log-in.

Samples were analyzed following the EPA Region I SOP, EIASOP-INGICP7.

Sample preparation was done following the EPA Region I SOP, INGMETALSPREP6.SOP.

Samples were analyzed by inductively coupled plasma - atomic emission spectrometry using pneumatic nebulization. Preparation and analysis SOP's are based on "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, SW-846, 3rd Edition, Revision 2, Final Update III, Methods 3050B and 6010B," respectively.

Date Samples Received by the Laboratory: 5/2/08

Results relate only to the items tested or to the samples as received by the Laboratory. This analytical report shall not be reproduced except in full, without written approval of the laboratory.

Report may contain multiple sections and each section will be numbered independently.

If you have any questions please call me at 617-918-8340

Sincerely,

Daniel N. Boudreau 6/30/08

Daniel N. Boudreau
Chemistry Team Leader

Qualifiers:

- RL** Reporting limit
- ND** Not Detected above reporting limit
- NA** Not Applicable
- NC** Not calculated since analyte concentration is ND
- J1** Estimated value due to MS recovery outside acceptance criteria
- J2** Estimated value due to LFB result outside acceptance criteria
- J3** Estimated value due to RPD result outside acceptance criteria
- J4** Estimated value due to LCS result outside acceptance criteria
- B** Analyte is associated with the lab blank or trip blank contamination. Values are qualified when the observed concentration of the contamination in the sample extract is less than 10 times the concentration in the blank.
- R** No recovery was calculated since the analyte concentration is greater than four times the spike level.

Comments:

The samples were prepared and analyzed by ESAT contractors.

Sample results are in mg/Kg, dry weight.

Only lead results were originally reported. The results for additional metals are included on this report as per Mike Daly's request.

F-2 SKEET RANGE

**NASB SKEET RANGE
CORRELATION OF FIXED BASED LABORATORY AND XRF LEAD
CONCENTRATIONS
NAVAL AIR STATION BRUNSWICK, MAINE**

To determine if the XRF lead concentrations can be used to predict fixed based laboratory concentrations a statistical correlation analysis was conducted. If the correlation between the XRF and fixed based laboratory concentrations is greater than or equal to 0.65 then the XRF concentrations can be used to predict fixed based laboratory concentrations. The correlation always falls between -1 and 1. Values of r near 0 indicate a very weak linear relationship. The strength of the linear relationship increases as r moves away from 0 toward either -1 or 1. Values of r close to -1 and 1 indicate that the points lie close to a straight line. The extreme values -1 and 1 occur only in the case of a perfect linear relationship. So the correlation indicates a strong linear trend. The R^2 value represents the percent of variation in laboratory concentrations that can be explained by the XRF concentration. An R^2 -value greater than approximately 80 percent is considered to indicate a very strong relationship between the two measurement methods. The maximum possible value is 100 percent. Recall that the XRF samples and fixed based data were not collected from the same sample as typical. The primary purpose of the XRF for this project was to confirm the location and boundaries of the skeet range; first XRF samples were collected and, at a later date, fixed based data were collected. Therefore, correlations for lead were expected to be somewhat lower than typical.

Figure 1 is a scatterplot of the XRF lead concentrations and the corresponding fixed based laboratory lead concentrations for each sample where both XRF and fixed based data are available. From the scatterplot, a linear trend is evident. The correlation is 0.25 indicating a weak linear relationship between the XRF and laboratory concentrations. However, there is a wide range of concentrations; XRF concentrations range from 18 to 1,839 mg/kg and fixed based laboratory concentrations range from 3.8 to 29,300 mg/kg. There appear to be two groups of data concentrations; one grouping with XRF concentrations less than 100 mg/kg and another grouping with XRF concentrations greater than 100 mg/kg that warranted further evaluation.

Figure 2 is a scatterplot of the XRF lead concentrations and the corresponding fixed based laboratory lead concentrations for those samples with XRF concentrations less than 100 mg/kg. From the scatterplot, a linear trend is evident. The correlation is 0.78 indicating a good correlation. The correlation is greater than 0.65, as stipulated in the SAP; therefore, the XRF concentrations can be used to predict laboratory concentrations where XRF concentrations are less than 100 mg/kg. Table 1 presents the predicted laboratory concentrations for the XRF concentrations that are less than 100 mg/kg where no laboratory concentrations are available. (For concentrations where the predicted laboratory concentration was negative, zero was used as the concentration).

Figure 3 is a scatterplot of the XRF lead concentrations and the corresponding laboratory lead concentrations for those samples with XRF concentrations greater than 100 mg/kg. From the scatterplot a linear trend is evident. The correlation is 0.062 indicating a very weak correlation; therefore, the XRF concentrations cannot be used to predict laboratory concentrations where XRF concentrations are greater than 100 mg/kg. However, for every sample where the XRF concentration was greater than 100 mg/kg in the scatterplot, the corresponding laboratory concentration was greater than the project action limit (PAL) of 40 mg/kg. Therefore, although XRF data with concentrations greater than 100 mg/kg were unable to be statistically correlated,

the XRF data is all usable, although with qualification. Table 2 presents the predicted laboratory concentrations for the XRF concentrations that are greater than 100 mg/kg where no laboratory concentrations are available; all predicted concentrations are qualified as "greater than the PAL of 40 mg/kg."

APPENDIX H

RESPONSES TO STAKEHOLDER COMMENTS OF DRAFT VERSION OF SI REPORT

RESPONSE TO MEDEP COMMENTS DATED OCTOBER 11, 2011
SITE INSPECTION REPORT FOR MUNITIONS RESPONSE PROGRAM SITES
MACHINE GUN BORESIGHT RANGE AND SKEET RANGE, DATED AUGUST 2011
FORMER NAVAL AIR STATION, BRUNSWICK
BRUNSWICK, MAINE

Note that where the comment response provides revised text, text additions are shown in bold italics and deleted text is shown as strikethrough.

General Comments:

1. **Comment:** MEDEP finds it difficult to read the numbers in the various tables that have been highlighted in red. If it is not too much effort, please use yellow highlighting in the final report.

Response: The red highlighting has been changed to yellow highlighting on all frequency of detection and positive detection tables (Tables 4-4, 4-5, 4-6, 4-7, 5-4, and 5-5).

2. **Comment:** MEDEP appreciates that all the detections are shown on the tag maps but it would be helpful to highlight (in yellow) the detections exceeding their screening criteria.

Response: Because some analytes exceeded multiple criteria, multiple formatting would make the tag figures very hard to read; therefore, the highlighting and other formatting have been presented on the frequency of detection and positive detection tables, but not on the positive detection figures. Note the screening criteria presented in the report are those criteria in place when SI Report was compiled and include, the USEPA Regional Screening Levels (RSLs) (June 2011), Federal Maximum Contaminant Levels (MCLs) (January 2011), Maine CDC Maximum Exposure Guidelines (MEG) for Drinking Water (February, 2011), and Maine RAGS, Appendix 3, (January 2010).

3. **Comment:** The Background Study should be finalized and then referenced for comparison in addition to the site-specific location chosen for sampling. This was proposed in response to comment (RTC) #15 in Appendix D in the Sampling and Analysis Plan (SAP).

Response: The Background Study was not finalized until March 2012, after the Draft SI Report was issued in August 2011. (It was incorrectly assumed during the SAP that facility background concentrations would be available for the report). Therefore, it is not recommended that the report be rewritten, considering that conclusions and results of the SI Report would remain the same.

Moreover, the Base Skeet Range SI has been superseded by the RI and the RI combines the SI and RI data sets for evaluation purposes, and does consider the final Background Study, as well as updated criteria, for evaluation purposes.

For the Machine Gun Boresight Range, the SI has been superseded by a successful removal action for the two soil hot spots identified during the SI. Now that final facility background values are available, additional evaluation is provided as follows:

For soil at the Machine Gun Boresight Range, the recommendations of Section 4.7 currently state:

"There are two "hot spots" of lead and other metals contamination in surface soil (SB22 and SB01), although the locations are infrequent and sporadic (not adjacent to each other). While it appears that metals contamination is present in soil at and near the former source berm location, the berm material has been removed and the remaining contamination is residual and limited to a small area."

Table 4-4 of the SI Report indicates that cadmium, chromium, lead, and nickel exceed the Maine RAGS (Appendix 3, January 2010), which is the most recent version of the RAGS. Facility background concentrations for each of these metals are less than Maine RAGS.

Parameter	Maximum Result, mg/kg	Maine RAGS, mg/kg January 2010	Final Facility Background, mg/kg (Upper Sand)
Cadmium	22	2.1	0.048
Chromium	320	100	16.2
Lead	1640	170	18 (surface soil) 3.4 (subsurface soil)
Nickel	430	100	9.8

For groundwater at the Machine Gun Boresight Range, the recommendations of Section 4.7 currently state:

"For groundwater, lead concentrations were not of concern, and only chromium and manganese were detected at concentrations greater than both Maine MEGs and USEPA tapwater RSLs. However, chromium was only a potential concern at one location (MW03); moreover, the concentration of chromium at this location was 35.1 micrograms per liter ($\mu\text{g}/\text{L}$), only slightly exceeding the Maine MEG value of 20 $\mu\text{g}/\text{L}$, while the maximum concentration of manganese, 551 $\mu\text{g}/\text{L}$, was only slightly greater than the Maine MEG of 500 $\mu\text{g}/\text{L}$. There were no analytes detected at concentrations greater than MCLs."

For reference purposes, the facility background concentration (Upper Sand) for chromium is nondetect. The facility background concentration for manganese is 173 and 432 $\mu\text{g}/\text{L}$ total and dissolved, respectively. Of note, the updated Maine MEG values of October 19, 2012 remain the same for chromium and manganese.

4. **Comment:** The statements regarding the impacts to groundwater when soil is only contaminated near the surface need to be qualified based on data from areas such as Site 7 where fairly low soil impacts near the surface can result in persistent groundwater contamination. The Machine Gun Boresight Range (MGBR) cadmium detection may need to be verified if groundwater will not be restricted near the MGBR.

Response: Several investigations were performed at Site 7 in an attempt to identify and remove a potential soil source of continuing elevated cadmium concentrations in

groundwater; however, no obvious source area for the elevated cadmium concentrations in groundwater was identified. At Site 7, it was determined that cadmium levels of 2.5 mg/kg or higher could result in groundwater concentrations above the MEG of 1 ug/l (the EPA health advisory number is 5 ug/l); moreover, cadmium was present in groundwater up to 40 ug/L. For groundwater at MGBR, the maximum cadmium concentration of 0.307 J ug/L is less than the MEG for drinking water (1 ug/L). For soil at MGBR, the maximum concentration of cadmium in soil was 22 mg/kg; cadmium was detected in 17 of 33 samples but only three of the locations exceeded 2.5 mg/kg. Of these three locations, two were co-located with the two identified hot spots for lead at locations since removed for remediation purposes, SB22 and SB01 surface soil samples, with cadmium concentrations of 22 and 4.9 mg/kg, respectively; the remaining location SB07 surface soil had a cadmium concentration of 6.29 J mg/kg, compared to the Maine RAGS of 2.1 mg/kg and USEPA RSL of 7 mg/kg). Therefore, considering MGBR post-remediation conditions for soil in combination with the low concentration of in groundwater, cadmium in groundwater does not appear to be impacted by cadmium in soil at MGBR.

It is noted that cadmium detections in groundwater at MGBR may need to be verified if groundwater use is not restricted near MGBR.

Specific Comments:

5. **Comment:** Executive Summary Table ES-1, Skeet Range, Surface Water and Sediment: The subheadings and the following sentences are switched.

Response: The sentences have been revised in both ES-1 and Section 5.7:

“Surface Water: Metals were detected at elevated concentrations in **surface water** sediment.

Sediment: Metals were detected at elevated concentrations in **sediment** surface water.”

6. **Comment:** Section 1.1, Purpose of Report: Please add the title of the workplan to the introduction.

Response: The first sentence of the second paragraph in Section 1.1 has been revised, “Field activities included MC sampling and analysis of surface soil, subsurface soil, sediment, and surface water samples, and well installation and groundwater samples at MGBR **which were conducted in accordance with the Site Inspection (SI) Work Plan, Munitions Constituents at Three Munitions Response Sites (Tetra Tech, 2009).**”

7. **Comment:** Section 1.3, Objectives: Please add the workplan objectives, verbatim, to this section.

Response: The first sentence of Section 1.3 has been revised (largely verbatim from the SI workplan although the workplan was referring to all three small arms ranges so objectives were tweaked a bit from the original): “**The objective of the SI described was to conduct**

an on-site investigation and gather sufficient data to determine the presence or absence of MC that may remain from activities conducted by the DoD during site operation and that may subsequently pose a threat to human health and/or the environment (Tetra Tech, 2009). Under the MRP, the primary goal of the SI is to collect the appropriate amount of information necessary to make one of the following decisions: 1) whether a Remedial Investigation (RI) is required at a site; 2) whether an immediate response is needed; or 3) whether the site qualifies for no further action (NFA). The main objective of the SI was to build on the PA information by gathering initial field data to determine whether MC (e.g., metals, explosives, propellants, and PAHs) that may have originated from previous site operations are present and potentially contributing to environmental impacts in surface soil, subsurface soil, surface water, groundwater, and sediment. Based on the results of the SI, recommendations establishing the path forward considering MC concerns for each MRS were developed, as applicable.

8. Section 2.2.5, Hydrology:

- a.) **Comment:** It is important to the Conceptual Site Model to mention Merriconeag Stream and its unnamed tributaries of which the impoundment ponds are a part.

Response: Subsection 2.2.5, Hydrology of Section 2.2, General Facility Physical/Environmental Characteristics, mentions Merriconeag Stream and its unnamed tributaries, "Merriconeag Stream and a number of other very small intermittent streams flow into Mere Brook, which flows into Harpswell Cove at the head of the cove."

The Hydrology section of Table 5-10, Conceptual Site Model Information Profile, Skeet Range, has been revised to include mention of Merriconeag Stream and its unnamed tributaries, "Surface water flows towards the retention ponds, **which are a part of the Merriconeag Stream watershed.**"

- b.) **Comment:** para. 1: There appears to be text missing on page 2-8 for the Mere Brook description. It should read "Mere Brook enters as a natural stream and is culverted under the runways to an outfall to the southeast" or something similar. Please revise the text.

Response: The fifth sentence of the first paragraph of Section 2.2.5 has been revised, "Mere Brook enters former NASB at the northwestern boundary and flows in its **as a natural streambed and is culverted** for approximately 0.5 mile under the runways **to an outfall to the southeast** and **then** through the southern end of former NASB."

9. Comment: Section 3.1.9, Investigation Derived Waste: The RCRA number for the main base does not include the Topsham facility, so a temporary number will be needed for any waste shipped from that location.

Response: The comment has been noted for future work at the Topsham facility.

10. Comment: Section 4.1.3, Current Land Use and Anticipated Future Land Use: Please check this section for clarity.

Response: This section, as well as the CSM table, will be revised as follows:

"Currently, the site is not in use, **except for Building 55 that is leased**, but in the future **anticipated land use will include** ~~will have~~ developed buildings for business and technology industry use."

11. Comment: Section 4.2.3.1, Surface and Subsurface Soil Sampling: Since this investigation the Navy has completed the Background Study therefore in addition to the one location selected for this investigation the data from the Background Study must also be considered.

Response: Please see the Navy's response to your General Comment 3.

12. Section 4.3, Hydrogeology:

a.) **Comment:** Para 3 & 4 and Figures 4-4 and 4-5: The proximity of the wells and the flat water table are contributing to some unrealistic flow maps, particularly Figure 4-4, as it is very unlikely that groundwater is flowing west or "converging" as depicted. The area is too small to accurately depict groundwater flow therefore this uncertainty must be discussed and flow lines should be dashed on the figures to indicate that uncertainty. If groundwater becomes an issue it may be necessary to install additional wells or piezometers to determine groundwater flow at the MGBR.

Response: Flow lines have been revised as dashed on Figure 4-4, but not Figure 4-5. In addition, the following text revisions have been made:

Section 4.3, 3rd paragraph, 2nd sentence has been revised as follows: "The additional round of water levels on July 22, 2010, was collected to confirm conditions at the site, **based on the groundwater flow directions observed in December 2009. Given the small size of the area under investigation and low hydraulic gradient, some uncertainty may exist for the groundwater flow, specifically for the December 9, 2009 measurements.**"

Section 4.3, 4th paragraph, last sentence has been revised as follows: "**Regardless of the potential uncertainties of groundwater flow, specifically December 2009**, the overall groundwater flow..."

b.) **Comment:** Para 3: "Regardless, the overall groundwater flow for the areas is expected to be to the southeast toward Mere Brook based on topography and previous groundwater investigation at Site 1..."

Do you mean Site 11 or Site 13? Site 1 is too far south and on the edge of Mere Brook to be useful to determine groundwater flow for the MGBR area. It is more likely that shallow groundwater flow is to the impoundment ponds or Picnic Pond which is part of the Merriconeag Stream watershed. Please correct.

Response: The sentence has been revised as follows: "**Regardless of the potential uncertainties of groundwater flow, specifically December 2009**, the overall

groundwater flow for the area is expected to be to the ~~east~~-southeast toward Mere Brook ~~the retention ponds and/or Picnic Pond~~ based on topography and previous groundwater investigations *in the area of MGBR* at (Sites 411 and 13, south of the MGBR, and Site 9, north of the MGBR)."

13. Comment: Section 4.4.1 and Appendix F.1, Figure 1: The plot suggests that the data have a split correlation. The data from 0 – 500 ppm (XRF) should be correlated separately from the higher values. Calculated values for XRF data < 500 ppm should be recalculated with the new correlation equation. Data points above 500 ppm XRF can use the correlation as presented. Please revise the tables and figures, and provide the new correlation plot.

Response: There is only one sample concentration greater than 500 ppm (NASB-MGBR-XRF-SB01-1216 XRF lead concentration = 610 ppm). One sample concentration is not enough data to compute a correlation analysis. However, the sample concentration greater than 500 ppm (NASB-MGBR-XRF-SB01-1216) has been marked as a potential outlier and an additional plot has been added to Appendix F-1 showing the correlation analysis with this sample concentration removed. With the potential outlier removed the correlation is 1 and therefore predicted laboratory concentrations can be predicted for concentrations less than 500 ppm. Table 1 in Appendix F-1 has been updated to display predicted laboratory concentrations based on the regression equation without the potential outlier.

14. Comment: Section 4.4.2.1, last sentence: Nitroglycerin was detected in SS-08 also according to MEDEP's data and Table 4-5, please revise the text.

Response: Section 4.4.2.1 presents a discussion of analytes that exceeded screening criteria. Nitroglycerin was only detected at concentrations greater than screening criteria in sample NASB-MGBR-SS01-0003 and its duplicate. Nitroglycerin was detected in sample NASB-MGBR-SS08-0003; at a concentration of 0.55J mg/kg which is less than the USEPA RSL of 0.61 mg/kg. Therefore, no revision has been made to Section 4.4.2.1.

15. Comment: Section 4.4.2.2, Groundwater: Chromium was slightly elevated at MW-03, which also had an unusually high pH (around 9). It is possible this is a residual effect of the berm construction materials.

Response: The pH values measured in groundwater at MW-03 were elevated, ranging from 9.87 – 9.41, chromium may tend to precipitate at these elevated pH levels. It is unknown if this is a residual effect of the berm construction materials.

16. Comment: Section 4.7, Recommendations: This section is conclusions not recommendations, please correct and add the recommendations.

Response: Section 4.7 text has been revised to include recommendations as follows (Note that the remediation of the two soil hot spots has since been completed):

Soil: There are two “hot spots” of lead and other metals contamination in surface soil (SB22 and SB01), although the locations are infrequent and sporadic (not adjacent to each other).

While it appears that metals contamination is present in soil at and near the former source berm location, the berm material has been removed and the remaining contamination is residual and limited to **at**these two small areas. ***The two hot spots warrant remediation via excavation and proper disposal.***

Groundwater: For groundwater, lead concentrations were not of concern, and only chromium and manganese were detected at concentrations greater than both Maine MEGs and USEPA tapwater RSLs. However, chromium was only a potential concern at one location (MW03); moreover, the concentration of chromium at this location was 35.1 micrograms per liter ($\mu\text{g}/\text{L}$), only slightly exceeding the Maine MEG value of $20 \mu\text{g}/\text{L}$, while the maximum concentration of manganese, $551 \mu\text{g}/\text{L}$, was only slightly greater than the Maine MEG of $500 \mu\text{g}/\text{L}$. There were no analytes detected at concentrations greater than MCLs. ***The low levels of inorganics found in groundwater do warrant groundwater use restrictions.***

These revisions have also been made to the Executive Summary.

17. **Comment:** Table 4-4, Frequency of Detections in Soil, page 1 of 2: Why are some of the Maine RAGs highlighted? Please remove if it serves no purpose. If there is a rationale, please include in the footnotes or in a legend.

Response: Per the footnotes on Table 4-4, page 2, these values were highlighted red to indicate that concentrations were greater than Maine RAGS criterion; values were italicized if concentrations exceeded USEPA RSL. Per General Comment #1, the red highlighting has been changed to yellow highlighting. Additionally, per Specific Comment #26, maximum concentration, rather than the associated Maine RAG or USEPA RSL, has been highlighted.

18. **Comment:** Table 4-5, Summary of Detected Concentrations in Surface and Subsurface Soil: Please highlight the nitroglycerin exceedance of EPA's Residential Screening Limits (RSLs).

Response: Per footnotes on page 15 of Table 4-5, concentrations greater than USEPA RSLs have been italicized. The nitroglycerin concentration for sample NASB-MGBR-SS01-0003, its duplicate concentration, and the average concentration of these sample results have been italicized. The nitroglycerin concentration for sample NASB-MGBR-SS08-0003 did not exceed the USEPA RSL and, therefore, is not italicized.

19. **Comment:** Table 4-6, Frequency of Detection in Groundwater: There are columns for the Minimum and Maximum Non-Detections. Is this correct? If it is, please provide some explanation in a footnote.

Response: Correct, the seventh and eighth columns present the minimum non-detections and maximum non-detections, respectively. A footnote 4 has been added to Table 4-6, "***Minimum and maximum non-detections are for all samples in the data set.***" A similar footnote has been added to Tables 4-4, 5-4, 5-6, and 5-8.

20. **Comment:** Conceptual Site Model, Machine Gun Bore Sight Range, Figure 4-10: The

figure shows a line (purple) for the pre 1950 skeet range. Please check to see if this is correct.

Response: The purple line on Figure 4-10 represents the portion of the post-1950 skeet range boundary that crosses the Machine Gun Bore Sight Range. The blue line on Figure 4-10 has been revised to indicate that it represents the tree line and not the pre-1950 skeet range.

21. Table 4-8:

a.) **Comment:** It is possible the chromium is related to material in the berm or perhaps some steel projectile used when operational. Greater support is needed to discount the MGBR as the source, such as a possible source for the high pH related to a later use. Chromium did not appear in the shallow groundwater background samples.

Response: Please see the response to your Comment 15. For Table 4-8, Munitions/Release Profile, Associated MC, the following has been revised: “Note that chromium present in both soil and groundwater is not perceived to be related to MGBR operations, ***although MGBR should not be discounted as the source, such as a possible source for the elevated pH related to a later use.***”

b.) **Comment:** The hydrology section should at least note the ponds to the north.

Response: A sentence has been added to the hydrology section of Table 4-8, “***The Upper and Lower Impoundment ponds are located on the north of the site.***”

22. Comment: Section 5.1.2, Munitions Constituents: Please clarify the phrase “PAH treatment of runway runoff” used in the last sentence.

Response: The subject phrase has been revised as follows: “Of note, assessment of the contributory effects from PAHs from the SKT at the impoundment ponds is difficult due to other significant sources of potential PAH contamination including stormwater runoff and PAH treatment of runway runoff ***that potentially contains PAHs.***”

23. Comment: Section 5.3, Geology Evaluation: Please check the first sentence for clarity.

Response: The first sentence of Section 5.3 has been revised, “The site is relatively level in the area of the former shooting stations ***skeet range high house and low house***”.

24. Comment: Section 5.3 Geology, para. 3: The description of the hydrogeology should refer to Site 13 or 11 (See comment 12.b above.) rather than Site 1, and MEDEP suggests clarifying that generally groundwater flows to the southeast toward Merriconeag Stream, but adjacent the ponds and stream shallow flow is toward those surface waters.

Response: Paragraph three of Section 5.3 has been revised, “Note that hydrogeology was not investigated based on previous groundwater investigations north (Site 9) and south

(Sites 411 and 13) of the SKT,. Groundwater is expected to flow to the ~~east~~-southeast north toward ***the impoundment ponds and/or Picnic Pond Merriconeag Stream.***

- 25. Comment:** Section 5.4.1 and Appendix F.2: The methods used are okay for establishing approximate bounds, but the lack of split samples for the data limits its applicability. Also please add trend lines to the plots in the appendix.

Response: The regression lines have been added to the Figures in Appendix F.2.

- 26. Comment:** Table 5-4: The table needs to be revised to highlight the max results rather than the associated RAG.

Response: Table 5-4 has been revised, the maximum concentrations that exceed Maine RAGs are highlighted yellow rather than the associated Maine RAG criterion. Table 5-4 has also been revised so that maximum concentrations that exceed the USEPA RSL are italicized rather than the corresponding USEPA RSL criterion. Similar revisions have been made to Tables 4-4 and 4-6.

- 27. Comment:** Section 5.5.2, Sediment: “Several metals.” Rather than several MEDEP suggests that the Navy provide actual number of metals (17) (e.g. Seventeen metals...).

Response: The first sentence of Section 5.5.2 has been revised, “**Several Seventeen** metals (aluminum, antimony, arsenic, barium, beryllium, chromium, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, vanadium, and zinc) were detected in sediment samples at concentrations exceeding PALs.”

28. Section 5.7: Recommendations:

- a.) **Comment:** The section lacks recommendations. Please include.

Response: Section 5.7 text has been revised to include recommendations as follows (Note that the Remedial Investigation (RI) field work has since been completed and the RI Report is pending):

“Further characterization of shallow surface soil is recommended for the SKT.

Soil: Shallow surface soil (0 to 3 inches bgs) is contaminated with metals and PAHs (primarily antimony, arsenic, lead, and benzo(a)pyrene) at unacceptable concentrations. The contamination appears to be located within the combined middle area of the pre-1950 and post-1950 range fans overlap. Contamination is present from the firing points extending outward to encompass the shotfall zones in this central area. Additional shallow surface soil sampling to refine the area is recommended.

Analytes for further sampling should include antimony, arsenic, lead, and select PAHs.

Groundwater: Groundwater was not investigated, pending evaluation of soil results. Because only shallow surface soils (0 to 3 inches bgs) are of primary concern, it does not appear that contamination has migrated to deeper soils at concentrations of concern and, therefore, the migration pathway from soil to groundwater is not complete. ***Therefore, for groundwater no investigation is warranted.***

Surface Water: Metals were detected at elevated concentrations in ***surface water*** sediment. ***Further assessment is recommended for the site pond.***

Sediment: Metals were detected at elevated concentrations in ***sediment*** surface water. ***Further assessment is recommended for the site pond.***"

These revisions have also been made to the Executive Summary.

- b.) **Comment:** The surface water and sediment information are switched. Please correct.

Response: See response to Specific Comment #5.

29. Table 5-10, Conceptual Site Model Information Profile:

- a) **Comment:** Munitions/Release Profile, Migration Routes/Release Mechanisms, Findings: The finding is that the area is level but in actuality it is transected by a deeply incised drainage way so erosion of the embankment exists. It also overlooks that the retention pond is not self contained but is part of a drainage system that flows to Picnic Pond, Merriconeag Stream and Mere Brook. Please revise.

Response: The first two sentences have been revised, "The ***majority of the Skeet Range*** area is level, ~~so~~. A ***drainage is present south of Neptune Drive within the Skeet Range. The drainage is a natural feature and well vegetated, therefore,*** no significant run-off is anticipated ***from the Skeet Range.*** Run-off that does occur will flow into ***the retention ponds, which retain the majority of the surface water from this area for collection and reduction of suspended sediment.***"

- b) **Comment:** Physical Profile, Topography: The Skeet Range is not flat but is transected by a deeply incised drainage way. The description needs to include the slopes around the ponds and streams. Please correct.

Response: The topography section has been revised, "The ***majority of the Skeet Range is mainly flat*** is level. A ***northwest-southeast trending drainage is present south of Neptune Drive within the Skeet Range.***"

- c) **Comment:** Land Use and Exposure Profile, Current Land Use: The information provided is for future land use, please correct.

Response: The current land use information has been revised, "***The area is primarily undeveloped except for the northernmost portion, which contains a***

baseball field and is intersected by Neptune Drive. ~~In the future, most of the site will be used for business and technology industries, while the eastern portion will be used for outdoor recreation.”~~

- d) **Comment:** Land Use and Exposure Profile, Potential Future land Use: Planned future uses include Community Mixed Use, Recreation, and Business and Technology. Please revise.

Response: The potential future land use information has been revised, “**Potential future land use includes Community Mixed Use, Recreation, and Business and Technology.** ~~Potential future land use is assumed to be the same as planned land use.”~~

The last sentence of Section 5.1.3, Current Land Use and Anticipated Future Land Use has also been revised, “~~In the future, most of the SKT will be slated for business and technology industries use, while the eastern portion will be used for outdoor recreation~~**Planned future land uses include Community Mixed Use, Recreation, and Business and Technology.**

- e) **Comment:** Land Use and Exposure Profile, Potential Future Human Receptors: Please list: residents, workers, visitors, trespassers, maintenance workers, and contractors.

Response: The potential future resident information has been revised, “**Potential future human receptors include residents, workers, visitors, trespassers, maintenance workers, and contractors.** Same as currently planned.”

- f) **Comment:** Land Use and Exposure Profile, Potential Future Land Use Related Activities: Please specify: business and technology related industry, residential, outdoor recreation, retail, offices, and day care.

Response: The potential future land use related activities information has been revised, “**Potential future land use related activities include business and technology related industry, residential, outdoor recreation, retail, offices, and day care.** Same as currently planned.”

- g) **Comment:** Land Use and Exposure Profile, Zoning/Land Use Restriction: Site 9 falls within the former skeet range and has soil and groundwater restrictions and restrictions on groundwater for the Eastern Plume extend into this area also. Please correct.

Response: The land use and exposure profile, zoning/land use restriction information has been revised, “No site specific restrictions or access controls **exist for the Skeet Range. However, a portion of Site 9 lies within the Skeet Range site boundary and Site 9 has soil and groundwater restrictions. Additionally, the Eastern Plume, which has groundwater restrictions, extends into the Skeet**

Range.”

- h) **Comment:** Ecological Profile, Habitat Type: There are a number of habitat types within skeet range including an open water wetland (retention ponds), scrub shrub, open field and forested areas. Please revise.

Response: The habitat type information has been revised, “Scrub/shrub, ~~in~~ open field, **forested areas, and an open water** wetland area ~~nearby along with~~ (retention ponds).

- i) **Comment:** Ecological Profile, Ecological Receptors and Species of Special Concern: In Section 2.3.1 it states “The state-listed Blanding’s turtle and spotted turtle (threatened) may reside in wetlands, vernal pools, or streams on or near the former installation.” Please correct.

Response: The ecological receptors and species of special concern information has been revised, “Potential ecological receptors include indigenous species. **The state-listed Blanding’s turtle and spotted turtle (threatened) may reside in wetlands, vernal pools, or streams on or near the former installation.** ~~No species of special concern are known to be present at the site. Most of the site is planned for industrial use, and remediation of contaminated soil is being recommended.”~~

- j) **Comment:** General Exposure Profile: While the statement is correct is does not consider the recreational area and the Mixed Community Use area within the site. Please correct.

Response: The following has been added as the last sentence of the General Exposure Profile section, “**Future planned land use includes Community Mixed Use, Recreation, and Business and Technology.**”

30. **Comment:** Figure 5-6, Conceptual Site Model: Please add sediment to the current/future recreational user and to ecological receptors. Residential users must also be added as there are residences already along the northern boundary of the site.

Response: Ingestion and dermal contact of sediment have been added to the description for both the current/future recreational user and ecological receptors. Ingestion, dermal contact, mixed use, and inhalation of surface soil for current/future residential users have been added to Figure 5-6.
